Supplementary Material and Methods

Reverse transcriptase-polymerase chain reaction (RT-PCR)

Total RNA was isolated as described in the SV Total RNA Isolation System (Promega) with on-column DNase digestion. DNase-treated RNA (200 ng) was used for the first-strand cDNA synthesis by using Murine Leukaemia Virus Reverse Transcriptase and Oligo d(T)₁₆ (Applied Biosystems). One-tenth of the cDNA reaction was taken as PCR template and amplified for 25-35 cycles depending on the particular mRNA abundance with denature at 94°C for 15 seconds, annealing at 51°C to 66°C for 15 seconds according to the primers, and elongation at 72°C for 30 seconds. *GAPDH* or *TTN* was used as an internal control. The primer sequences (forward and reverse), the annealing temperatures, and the cycles used for RT-PCR analyses were listed in Table S2.

Immunocytochemical staining

Cultures at different stages were fixed with 4% paraformaldehyde (PFA, Sigma) in PBS at room temperature for 20 minutes, and then blocked with 1% BSA at 4°C overnight. The primary antibodies were used at the following dilutions: OCT4 (goat polyclonal antibody, 1:100, R&D), SOX2 (rabbit polyclonal antibody, 1:2000, Millipore), NANOG (goat polyclonal antibody, 1:200, R&D), LIN28 (goat polyclonal antibody, 1:100, R&D systems), stage-specific embryonic antigen 4 (SSEA4, mouse monoclonal IgG3, DSHB), TRA-1-60 (mouse monoclonal IgM, Millipore), α-actinin (mouse monoclonal IgG1, 1:1000, Sigma Aldrich), myosin light chain 2v (MLC2V, rabbit IgG antibody, 1:200, Proteintech, 10906-1-AP), myosin light chain 2a (MLC2A, mouse IgG2b antibody, 1:500, Synaptic Systems, 56F5), cardiac troponin T (cTNT, mouse monoclonal IgG1, 1:100, Neomarkers), smooth muscle-α-actin (α-SMA, mouse monoclonal IgG1, Sigma Aldrich), α-fetoprotein (AFP, rabbit polyclonal antibody, 1:300, Dako), and β-III-tubulin (mouse monoclonal IgG2a, 1:500, BAbCo). The primary antibodies were applied for 1 hour at 37°C or overnight at 4°C. The fluorescently labeled secondary antibodies with minimal cross reactivity were Cy3-conjugated donkey anti-goat IgG (1:600, for NANOG, OCT4, and LIN28), Cy3-conjugated goat anti-rabbit IgG (1:600, for SOX2, AFP, and MLC2V), and FITC-conjugated goat anti-mouse (1:200, for SSEA4, TRA-1-60, α-actinin, cTNT, MLC2A, α-SMA, and β-III-tubulin) from Dianova. The secondary antibodies were administered in 1% BSA for 1 hour at 37°C. Nuclei were count-stained with 4,6-diamino-2-phenylindole (DAPI, 0.2 ng/ml, Sigma Aldrich). Samples were mounted with VectaShield mounting medium (VECTOR Laboratories). For antibodies against OCT4, SOX2 and NANOG, the samples were initially permeabilized by incubation in 0.1% Triton X-100 (Sigma Aldrich) in PBS for 10 minutes at room temperature.

Images were analyzed using a fluorescence microscope (Axiovert 200, Zeiss). Detection of the FITC fluorophore was performed by using the filter sets with excitation BP 475/40, beam splitter FT 500 and emission BP 530/50. Detection of the Cy3 fluorophore was performed by using the filter sets with excitation BP 540/25, beam splitter FT 565 and emission BP 605/55. Detection of the DAPI fluorophore was performed by using the filter sets with excitation G 365, beam splitter FT 395 and emission BP 445/50.

Bisulfite sequencing assays

The DNA methylation analysis was conducted using bisulfite sequencing assays by Epigenomics (Berlin). Briefly, genomic DNA was isolated and purified from three independent cell lines of the patient with the mutation in *RBM20* (1-RBM20-2, -3, and -7) using QIAamp DNA Mini kit (Qiagen). Human ESC line HES3 was used as positive control.

The genomic DNA was then treated with sodium bisulfite. One region (399 bp, from -213 bp to +185 bp relative to the TSS) was studied in the *OCT4* (NM_002701) promoter at the minimal promoter (MP) containing the TSS. In addition, one region (443 bp, from -378 bp to +64 bp relative to the TSS) of the *NANOG* gene (NM_024865) was studied. The following primers (forward and reverse) designed for the regions of interest were used for PCR and for sequencing: *OCT4*: 5' GAT TTG TAT TGA GGT TTT GGA 3' and 5' TCC AAA AAA ACC TTA AAA ACT T 3'; *NANOG*: 5' TAA TTT CAA ACT CCT AAC TTC AAA TAA T 3' and 5' TAA TAT GAG GTA ATT AGT TTA GTT TAG T 3'.

Spontaneous in vitro differentiation

To study the *in vitro* differentiation potential of the generated iPSC lines, spontaneous differentiation using the embryoid body (EB) method was carried out. Briefly, iPSCs were dispersed with collagenase IV into small clumps and cultured in suspension in hESC medium for 1 day. To initiate differentiation, the formed EBs were then cultured in suspension for another 7 days in differentiation medium, consisting of Iscove's modified Dullbecco's medium (Thermo Fisher Scientific), 20% FCS, L-glutamine (2 mM), 1x NEAA, and monothioglycerol (450 µM, Sigma Aldrich). EBs at day 8 were then plated on 0.1% gelatin-coated dishes and cultured in differentiation medium for another 30 days. Tissue-specific genes and proteins were analyzed in EB outgrowths at different differentiation stages by RT-PCR and Immunocytochemical staining, respectively.

Teratoma formation

To investigate the developmental potential of reprogrammed clones *in vivo*, iPSCs (about 2x 6-cm dishes at 70% confluence for each mouse) were injected subcutaneously into 8-week-old immunodeficient mice (4 mice per cell line) as described previously [1, 2]. Six to eight weeks after injection the mice were sacrificed and the resulting teratomas were examined with hematoxylin and eosin staining.

Supplementary Figures

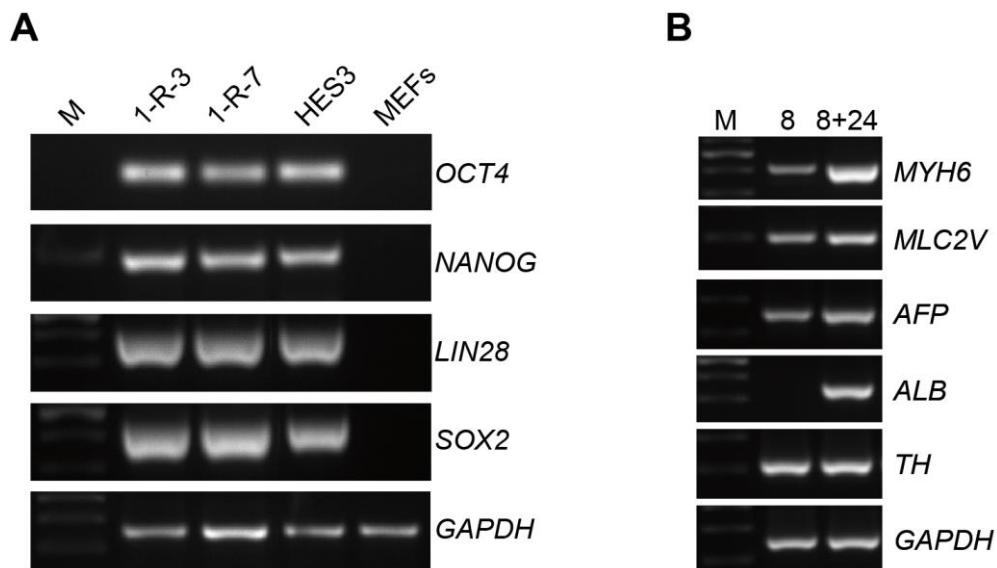

Figure S1: Proof of pluripotency. **A**, all RBM20-iPSC lines expressed endogenous pluripotency markers *OCT4*, *NANOG*, *LIN28*, and *SOX2* at higher levels than the parental fibroblasts (F-1-R) as shown by RT-PCR. GAPDH was used as loading control. HES3 cells and MEFs represent the positive and negative control, respectively. **B**, spontaneous differentiation capacity of RBM20-iPSC line 1-R-7. Germ layer-specific genes *MYH6*, *MLC2V* (mesoderm), *AFP*, *ALB* (endoderm), and *TH* (ectoderm) were expressed in a developmentally controlled manner during EB differentiation. GAPDH is included as loading control. Analyses were performed at different stages (days 8, 8+24) during differentiation of EBs after plating at day 8 (d8).

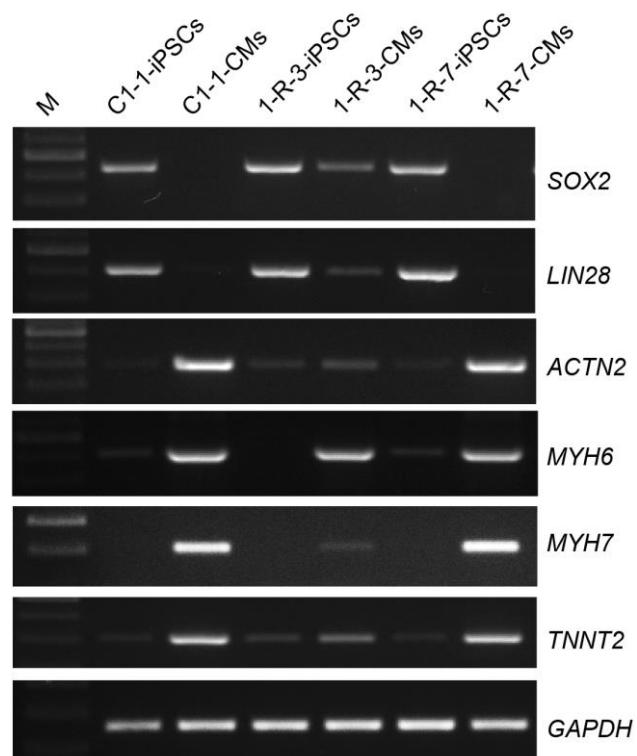

Figure S2: Expression of cardiac markers in RBM20- and control-iPSC-CMs. RT-PCR showing the expression of indicated genes in undifferentiated iPSCs and CMs differentiated from RBM20- and control-iPSCs. GAPDH was used as loading control.

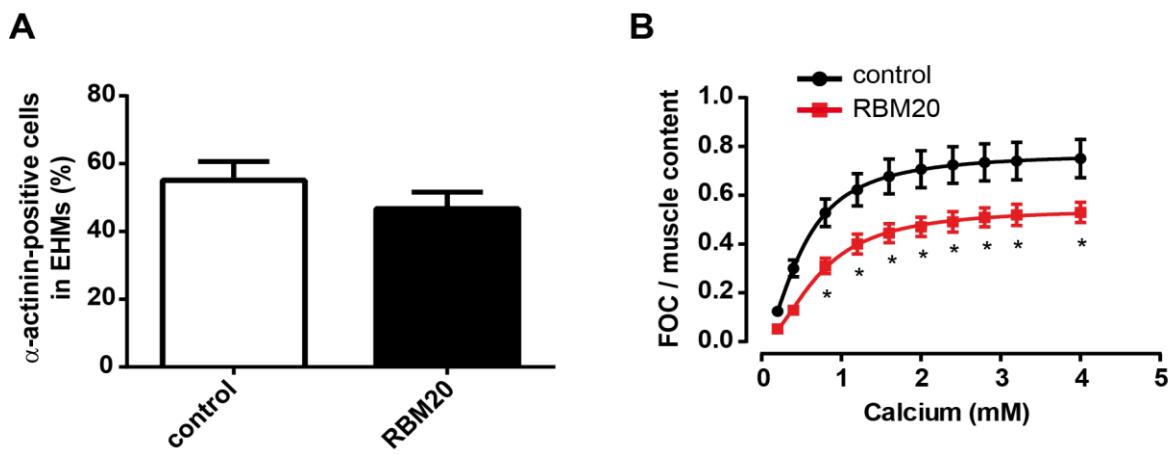

Figure S3: Functional phenotype of RBM20-EHMs. **A**, muscle contents of EHMs from RBM20- and control-iPSC-CMs as shown as the percentage of α -actinin-positive cells. **B**, force of contraction per muscle content (FOC/muscle content) of EHMs in response to increasing extracellular calcium concentration (0.2-4 mM) to assess the maximal inotropic capacity of EHMs. n=13 control-EHMs generated from 5 independent differentiation experiments with control iPSC lines C1-1 and C3-1; n=11 RBM20-EHMs generated from 3 independent differentiation experiments with RBM20-iPSC lines 1-R-2 and 1-R-3. *, P<0.05 RBM20 vs. control by two-way ANOVA.

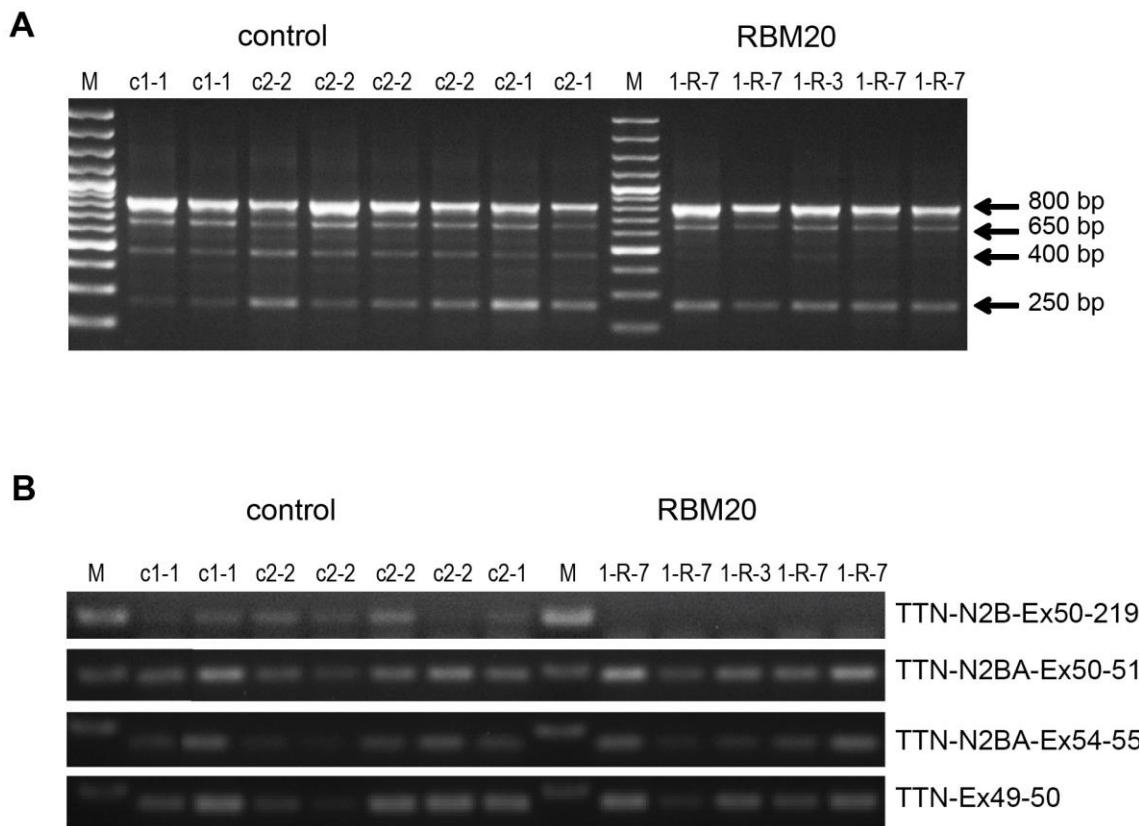

Figure S4: Semi-quantitative RT-PCR for *TTN* splicing variants in RBM20- and control-iPSC-CMs. RT-PCR of RBM20-iPSC-CMs and control-iPSC-CMs at day 60 of differentiation and relative densitometry to detect the titin splicing variants. **A**, primers were designed spanning exons 114-122 to quantify long and short *TTN* splicing isoforms with expected sizes of 250 bp, 400 bp, 650 bp, and 800 bp. The long isoform (800 bp) was used as internal control. For RBM20-iPSC-CMs, n=5 independent differentiation experiments from two cell lines 1-R-3 and 1-R-7 were studied, and for control-iPSC-CMs, n=8 independent differentiation experiments from three different control cell lines C1-1, C2-1 and C2-2 were investigated. **B**, *TTN-N2B* isoform is reduced in RBM20-iPSC-CMs in comparison to control-iPSC-CMs. Primers spanning *TTN* exons 49 and 50 were designed for amplifying total *TTN*, which was used as internal control. For expression of *TTN-N2B*, a primer pair spanning exons 50 and 219 was used. For *TTN-N2BA* variant expression, primers were designed spanning exons 50-51 and 54-55. For RBM20-iPSC-CMs, n=5 independent differentiation experiments from 2 different cell lines 1-R-3 and 1-R-7 were analyzed. For control-iPSC-CMs, n=7 independent differentiation experiments from 3 different cell lines C1-1, C2-1 and C2-2 were studied.

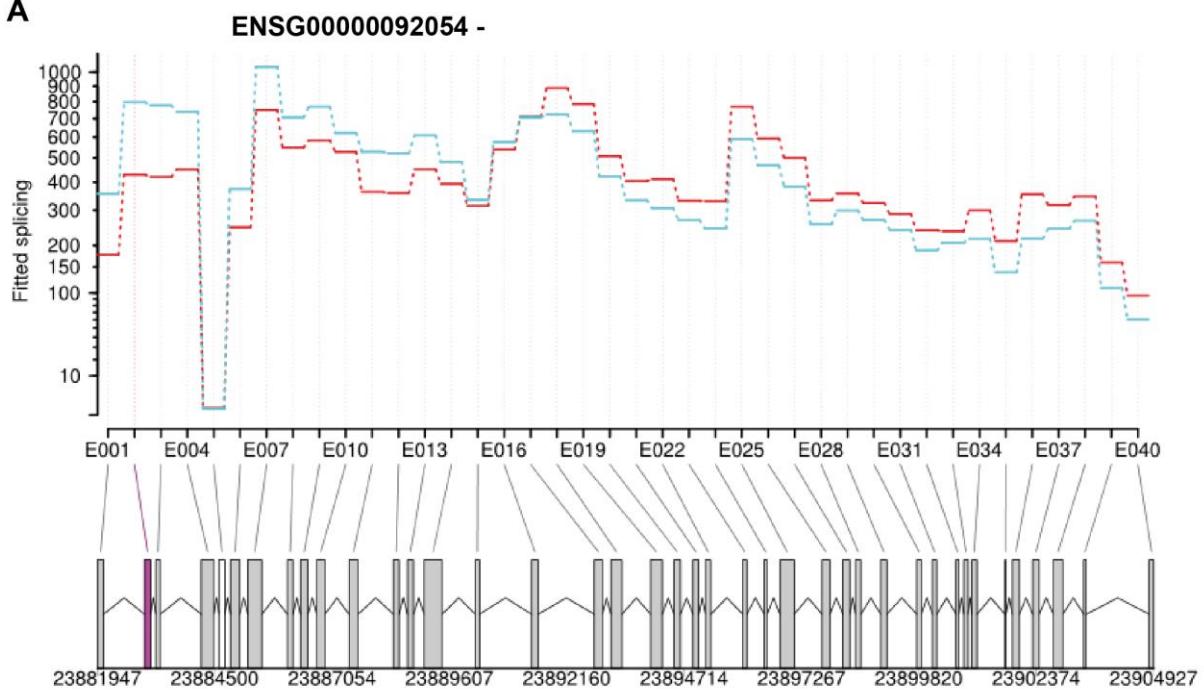

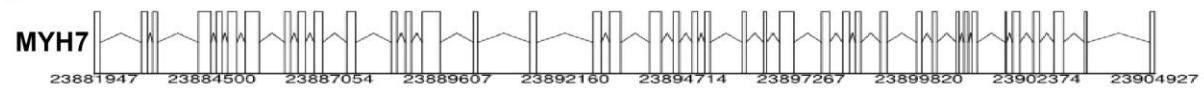

A**B**

Figure S5: RBM20-dependent exon expression of the *MYH7* gene. **A**, shown is lower expression of exon 2 (pink box) in RBM20-iPSC-CMs compared to control-iPSC-CMs. Red lines: patient, blue lines: control. **B**, the only isoform of the *MYH7* gene.

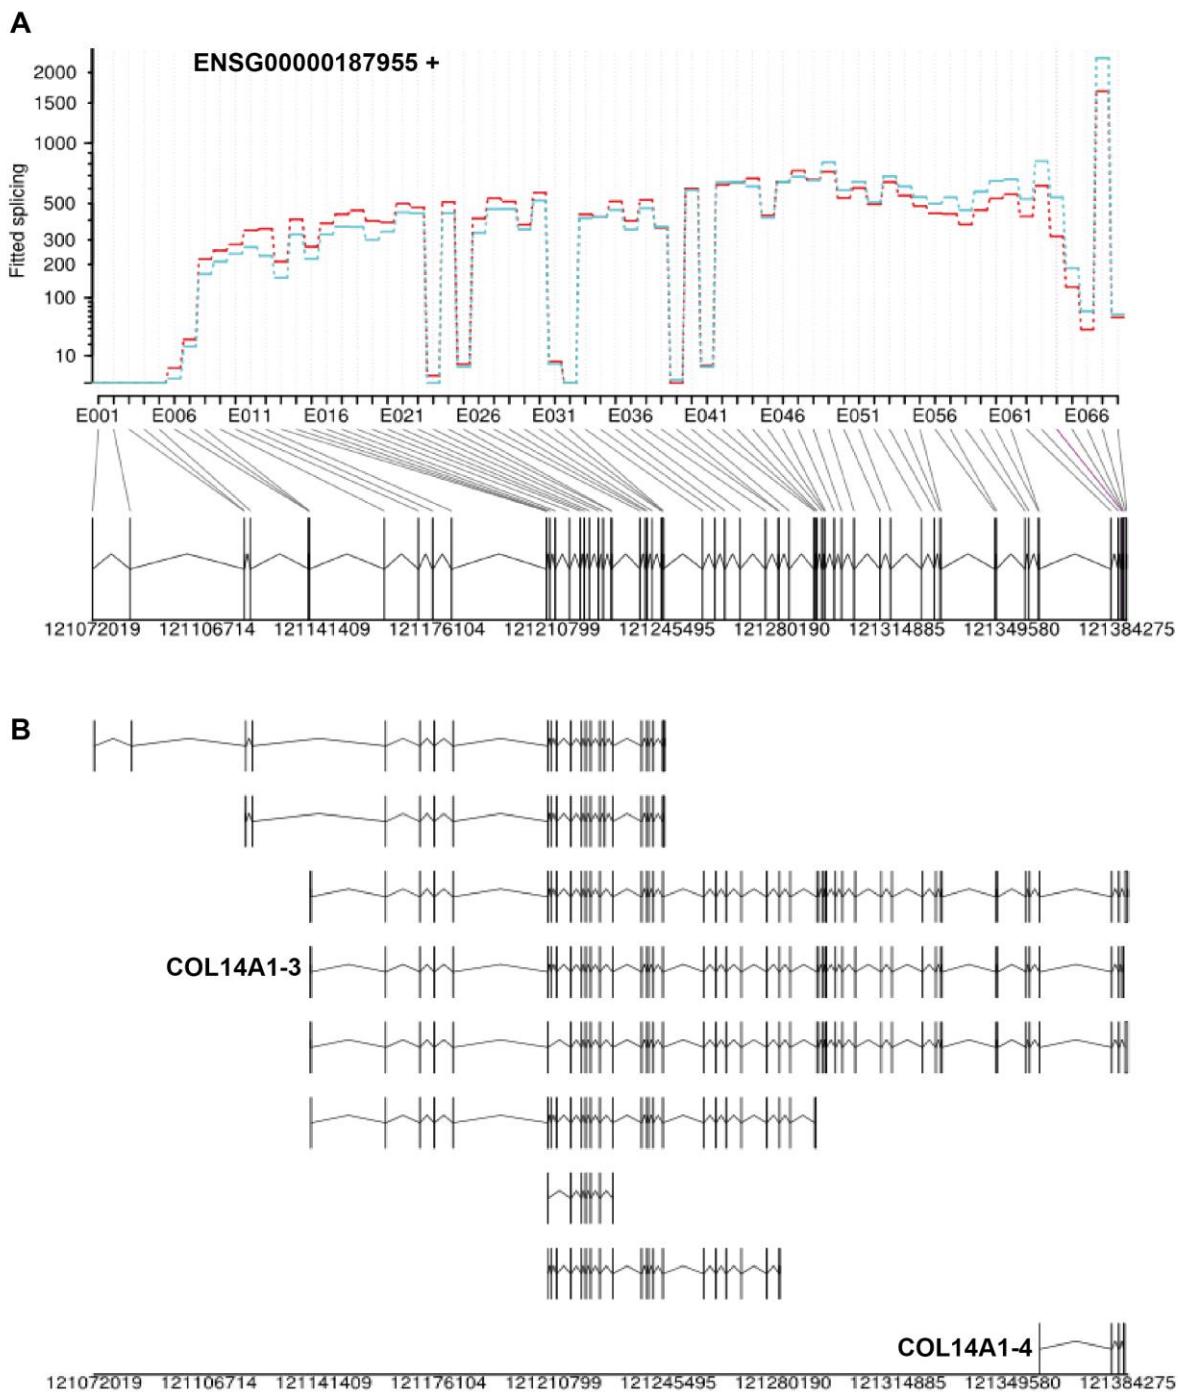

Figure S6: RBM20-dependent exon expression of the *COL14A1* gene. **A**, the gene *COL14A1* shows decreased expression of exon 64 (pink box) in RBM20-iPSC-CMs compared to control-iPSC-CMs. Red lines: patient, blue lines: control. **B**, different isoforms of the *COL14A1* gene. The decreased expression of exon 64 suggests an altered abundance of the isoforms 3 and 4 (*COL14A1-3* and *COL14A1-4*).

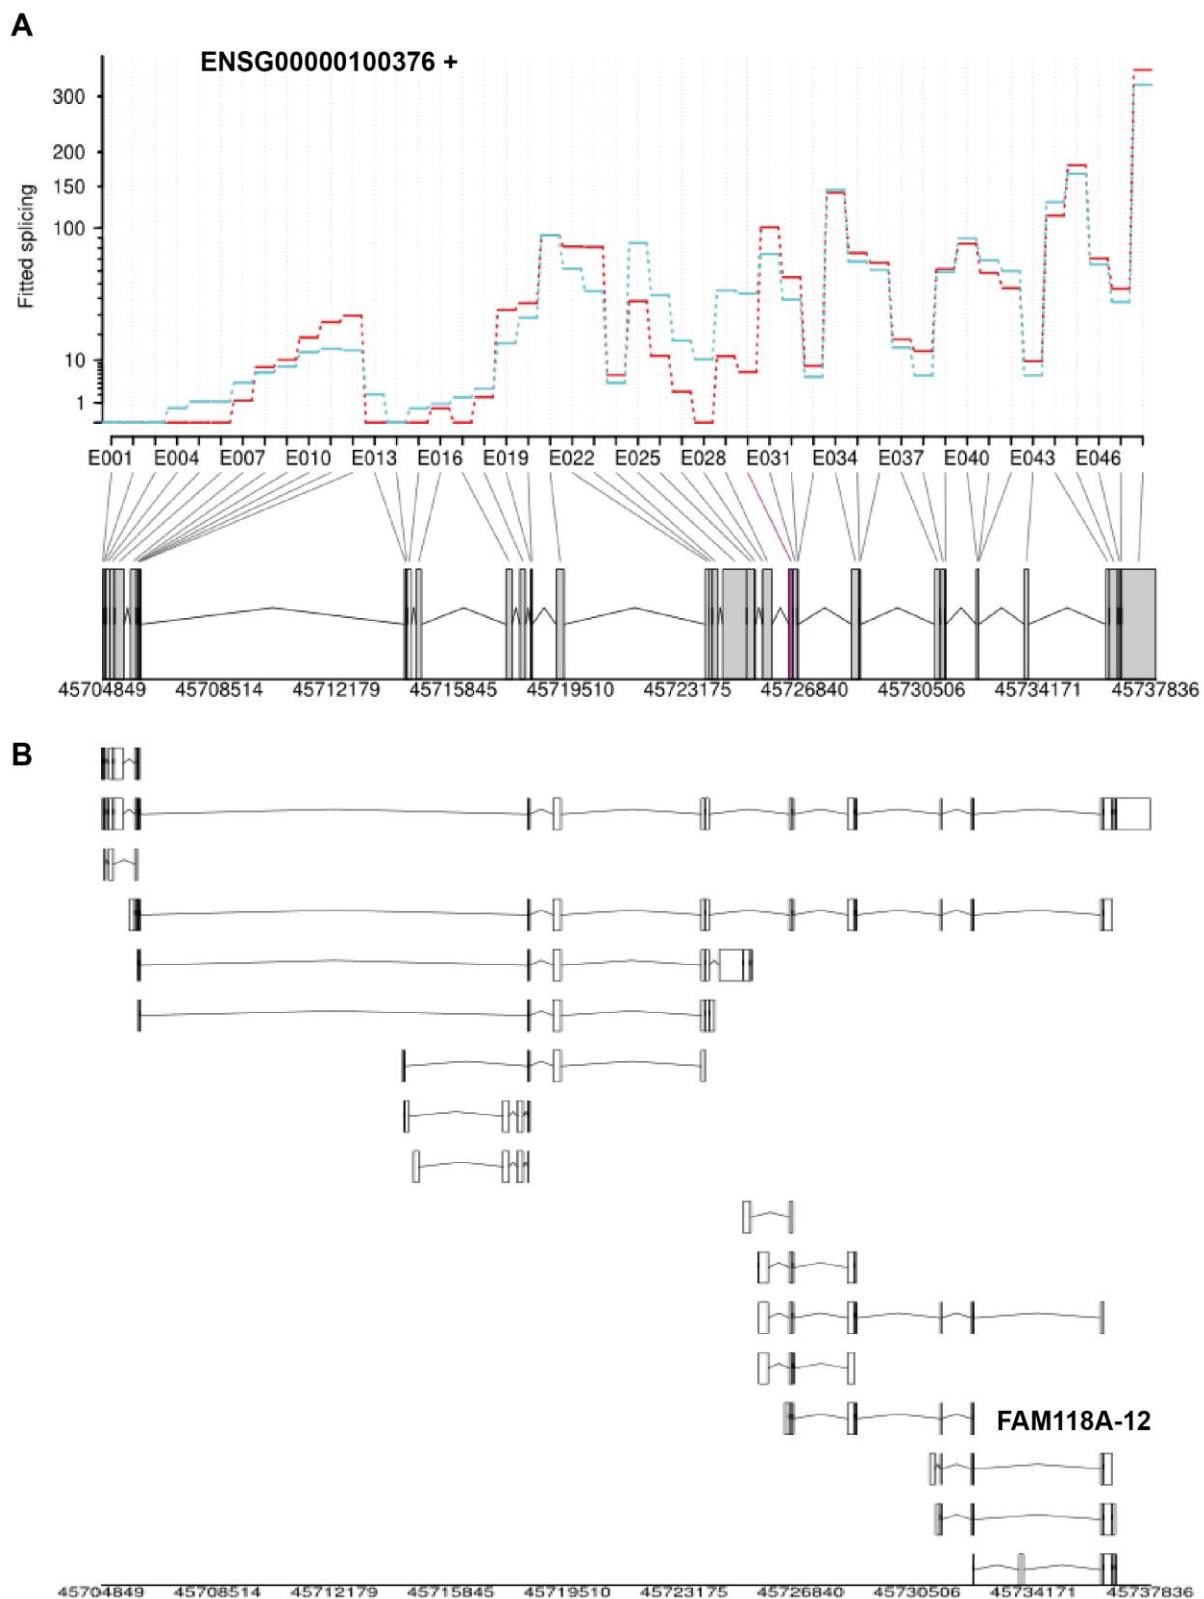

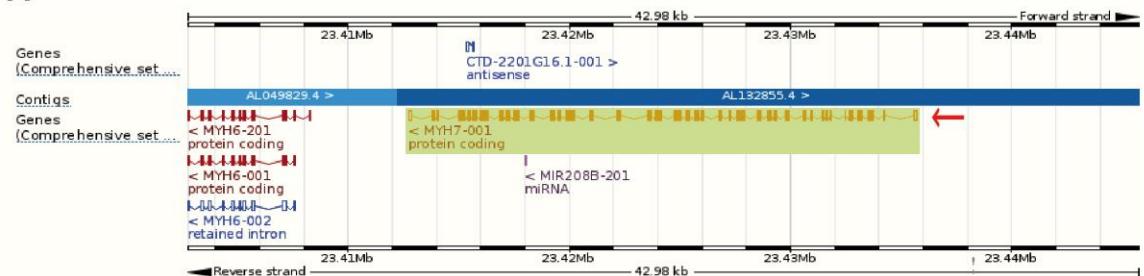

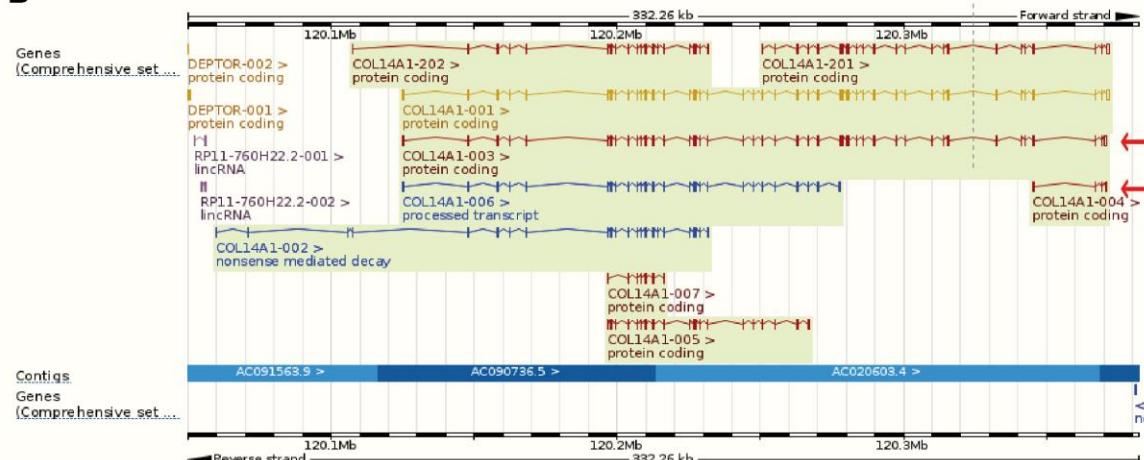

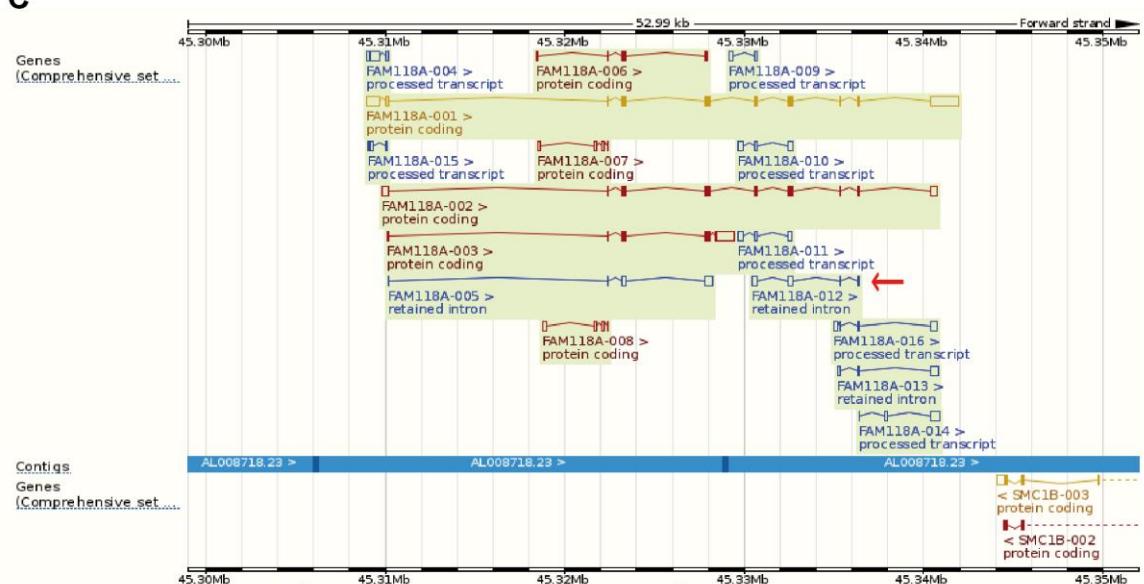

Figure S7: RBM20-dependent exon expression of the *FAM118A* gene. **A**, the gene *FAM118A* shows lower expression of exon 30 (pink box) in RBM20-iPSC-CMs. Red lines: patient, blue lines: control. **B**, different isoforms of the *FAM118A* gene. The decreased expression of exon 30 suggests lower abundance of the transcript of isoform 12 (*FAM118A-12*).

Figure S8: Genetic architecture and domain structure of *MYH7*, *COL14A1*, and *FAM118A*. The figure was downloaded from the ENSEMBL database (version e88). It shows the human genomic locus of *MYH7* (A), *COL14A1* (B), and *FAM118A* (C) and its annotated transcribed isoforms including exon structure and encoded protein domains. Isoforms 1 (*MYH7*), 12 (*FAM118A*), 3 and 4 (*COL14A1*) are marked with a red arrow. These were the isoforms of the three genes, whose expression might be influenced due to the differential exon usage in RBM20-CMs detected in RNA-seq data.
