26

27 **Abstract**

28 The paralogous human proteins UPF3A and UPF3B are involved in recognizing mRNAs
29 targeted by nonsense-mediated mRNA decay (NMD). While UPF3B has been demonstrated
30 to support NMD, contradicting reports describe UPF3A either as an NMD activator or inhibitor.
31 Here, we present a comprehensive functional analysis of UPF3A and UPF3B in human cells
32 using combinatory experimental approaches. Overexpression or knockout of UPF3A as well
33 as knockout of UPF3B did not detectably change global NMD activity. In contrast, the co-
34 depletion of UPF3A and UPF3B resulted in a marked NMD inhibition and a transcriptome-wide
35 upregulation of NMD substrates, demonstrating a functional redundancy between both NMD
36 factors. Although current models assume that UPF3 bridges NMD-activating exon-junction
37 complexes (EJC) to the NMD factor UPF2, UPF3B exhibited normal NMD activity in rescue
38 experiments when UPF2 or EJC binding was impaired. Further rescue experiments revealed
39 partially redundant functions of UPF3B domains in supporting NMD, involving both UPF2 and
40 EJC interaction sites and the central region of UPF3. Collectively, UPF3A and UPF3B serve
41 as fault-tolerant NMD activators in human cells.

42

43 Introduction

44 Precisely regulated expression of correct gene products is indispensable for eukaryotic life.
45 This is underlined by the existence of several quality control mechanisms for gene expression,
46 one of which is the nonsense-mediated mRNA decay (NMD). NMD is primarily known for its
47 ability to eliminate mature mRNAs that contain a premature termination codon (PTC). Thereby,
48 NMD prevents the synthesis and accumulation of C-terminally truncated proteins, which may
49 possess undesirable and potentially disease-causing properties (Frischmeyer & Dietz, 1999).
50 Although the removal of PTC-containing mRNAs was initially considered the most important
51 function of NMD, later studies showed that NMD plays an important role in the post-
52 transcriptional regulation of a substantial part of the transcriptome (He *et al.*, 2003; Lelivelt &
53 Culbertson, 1999; Mendell *et al.*, 2004; Rehwinkel *et al.*, 2005). The importance of the factors
54 involved in NMD is underscored by the severe impact that mutations in components of this
55 machinery have on development in metazoans, up to causing embryonic lethality in mammals
56 (Hwang & Maquat, 2011; Li *et al.*, 2015; McIlwain *et al.*, 2010; Medghalchi *et al.*, 2001;
57 Metzstein & Krasnow, 2006; Weischenfeldt *et al.*, 2008; Wittkopp *et al.*, 2009).

58 The final step of gene expression is the cytoplasmic translation of the mRNA by ribosomes.
59 Previous studies suggested that prolonged ribosome stalling at a termination codon indicates
60 improper translation termination and thereby triggers NMD (Amrani *et al.*, 2004; Peixeiro *et al.*,
61 2012). This could be caused by a long 3' untranslated region (UTR) that increases the distance
62 between the stalled ribosome and the poly(A)-binding protein (PABPC1), which normally
63 promotes proper translation termination (Amrani *et al.*, 2004). Alternatively, NMD can also be
64 activated by any PTC located more than 50-55 nt upstream of the 3'-most exon-exon junction.
65 Transcripts with such a PTC may be transcribed from mutant genes with nonsense mutations
66 but could also be generated by defective or alternative splicing (Kervestin & Jacobson, 2012).
67 The aforementioned 50-55 nt boundary between NMD-activating and NMD-resistant PTCs is
68 determined by the RNA-binding exon junction complex (EJC), which is deposited by the
69 spliceosome 20-24 nt upstream of every spliced exon-exon junction (Le Hir *et al.*, 2000). The

70 EJCs remain attached on the mature mRNA during export into the cytoplasm, where they are
71 removed by translating ribosomes or the disassembly factor PYM1 (Dostie & Dreyfuss, 2002;
72 Le Hir *et al.*, 2000). If translation terminates prematurely due to the presence of a PTC, EJCs
73 bound downstream of the PTC serve as a marker for the NMD machinery and the initial
74 activation of NMD (Kim *et al.*, 2001; Le Hir *et al.*, 2001).

75 Extensive research over many decades has resulted in a model for EJC-dependent NMD.
76 According to this model, the central factor UPF1 is bound non-specifically to all present
77 transcripts in the cell and is removed from the coding sequence by translating ribosomes (Hogg
78 & Goff, 2010; Hurt *et al.*, 2013; Kurosaki & Maquat, 2013; Zund *et al.*, 2013). If translation
79 terminates prematurely, UPF1 interacts with the stalled ribosome and serves as the anchoring
80 point for the other NMD factors. The presence of a downstream EJC is detected by the
81 interaction of UPF1 with UPF2, which in turn binds to UPF3. The latter can bind directly to the
82 EJC, resulting in a bridged connection of UPF1 to the EJC (Chamieh *et al.*, 2008; Kim *et al.*,
83 2001; Le Hir *et al.*, 2001; Weng *et al.*, 1996). This series of interactions marks the termination
84 codon as premature and stimulates the phosphorylation of N- and C-terminal SQ motif-
85 containing regions of UPF1 by the kinase SMG1 (Yamashita *et al.*, 2001). In its phosphorylated
86 state UPF1 recruits the heterodimer SMG5-SMG7 and/or SMG6, which are responsible for
87 both exoribonucleolytic and endoribonucleolytic degradation of the mRNA, respectively
88 (Boehm *et al.*, 2021; Chen & Shyu, 2003; Lejeune *et al.*, 2003). The endonuclease SMG6
89 cleaves the mRNA in close proximity to the PTC, resulting in two mRNA fragments (Eberle *et*
90 *al.*, 2009) of which the 3' fragment is degraded by the 5'-to-3' exoribonuclease XRN1 (Eberle
91 *et al.*, 2009; Huntzinger *et al.*, 2008).

92 The protein UPF3 plays an important role in the NMD pathway. As detailed above, its main
93 function is believed to bridge the NMD machinery to the EJC providing a physical link between
94 UPF2 and the EJC (Chamieh *et al.*, 2008; Kashima *et al.*, 2006; Lykke-Andersen *et al.*, 2000;
95 Serin *et al.*, 2001). With its conserved RNA recognition motif (RRM) in the N-terminus, UPF3
96 can interact with the C-terminal MIF4G (middle portion of eIF4G) domain of UPF2 (Kadlec *et*

97 *al.*, 2004). The association with the EJC-binding site, formed by the core components EIF4A3,
98 MAGOHB and RBM8A, is enabled by a C-terminal sequence referred to as EJC binding motif
99 (EBM) (Buchwald *et al.*, 2010; Gehring *et al.*, 2003; Kim *et al.*, 2001).

100 In vertebrates two genes encode for two UPF3 paralogues: UPF3A and UPF3B, each of which
101 expressing two different isoforms generated by alternative splicing (Lykke-Andersen *et al.*,
102 2000; Serin *et al.*, 2001). Both human UPF3 proteins contain the same important domains, but
103 differ in details regarding their interactions. According to previous studies, UPF3A and UPF3B
104 are in constant competition for their binding partner UPF2. However, UPF3B binds tighter to
105 UPF2 than UPF3A and therefore UPF3A gets destabilized, and its protein levels are barely
106 detectable under normal conditions (Chan *et al.*, 2009).

107 Recently, UPF3B was reported to interact with the eukaryotic release factor 3 (eRF3) via the
108 so far uncharacterized middle domain (amino acids (aa) 147-256) (Neu-Yilik *et al.*, 2017). Due
109 to this interaction and binding of the terminating ribosome, it can delay translation termination,
110 which is known to define aberrant termination events and trigger NMD (Amrani *et al.*, 2004;
111 Neu-Yilik *et al.*, 2017; Peixeiro *et al.*, 2012).

112 Due to the different molecular characteristics of the UPF3 paralogs, their exact role in NMD is
113 a long-discussed topic. On the one hand, previous studies showed that UPF3A and UPF3B
114 both trigger degradation of a reporter construct when tethered downstream of a termination
115 codon. Notably, the efficiency of UPF3A to elicit NMD was weaker in comparison to UPF3B,
116 which was attributed to a weaker interaction with the EJC (Kunz *et al.*, 2006; Lykke-Andersen
117 *et al.*, 2000). This would suggest that, at least with respect to their NMD activity, UPF3A and
118 UPF3B serve a similar, perhaps even redundant, function. This notion is supported by the
119 observation that in patients with mutated UPF3B the amount of stabilized UPF3A inversely
120 correlated with the severity of the patients' clinical phenotypes (Nguyen *et al.*, 2012). On the
121 other hand, it was recently reported that loss of UPF3A results in increased transcript
122 destabilization, and UFP3A overexpression in NMD inhibition (Shum *et al.*, 2016). This would

123 rather indicate opposing functions of the two UPF3 paralogs with UPF3A being an antagonist
124 of UPF3B and broadly acting as an NMD inhibitor.

125 In this study, we resolved the controversy about the functions of UPF3A and UPF3B in the
126 NMD pathway using different UPF3 overexpression and knockout (KO) HEK293 cell lines. We
127 found that neither overexpression nor genomic KO of UPF3A resulted in substantial changes
128 of NMD activity or global alterations of the transcriptome. In UPF3B KO cells UPF3A protein
129 levels were upregulated, but NMD activity was maintained at almost normal level. In contrast,
130 the co-depletion of both UPF3 paralogs resulted in a marked NMD inhibition and a global
131 upregulation of PTC-containing transcripts. Moreover, rescue experiments revealed that UPF3
132 proteins have additional functions besides bridging the EJC and the NMD machinery. Taken
133 together, our data support a model of human NMD, in which UPF3A and UPF3B can replace
134 each other and therefore perform redundant functions.

135 **RESULTS**

136 **UPF3A overexpression or knockout does not affect NMD efficiency**

137 Prior work using different mammalian models and various experimental approaches reached
138 different conclusions regarding the function of UPF3A in NMD ([Fig 1A](#)). Therefore, we set out
139 to re-examine the role of UPF3A in human cells by specifically manipulating its expression
140 levels. Under regular conditions UPF3A is barely present in cultured cells, presumably due to
141 its lower binding affinity to the stabilizing interaction partner UPF2 compared to UPF3B,
142 resulting in a rapid turnover of “free” UPF3A (*Chan et al.*, 2009). We hypothesized that
143 increasing the abundance of UPF3A should lead to the stabilization of NMD targets if UPF3A
144 is an NMD inhibitor. To test this hypothesis, we generated Flp-In T-REx 293 (HEK 293) cells
145 inducibly overexpressing FLAG-tagged wildtype UPF3A to high protein levels ([Fig 1B](#)). Global
146 analysis of the transcriptome using RNA-seq ([Fig EV1A](#) and [Datasets EV1-EV3](#)) revealed,
147 except for UPF3A itself, no significant differential gene expression (DGE), differential transcript
148 usage (DTU) or alternative splicing (AS) events upon UPF3A overexpression compared to
149 control conditions ([Figs 1C](#) and [D](#)). Using these RNA-seq data, we analyzed NMD targets that
150 were previously described to be strongly upregulated in UPF3A overexpressing HeLa cells
151 (*Shum et al.*, 2016). The DGE analysis and visualization of the respective read coverage
152 showed no substantial effects in our setup ([Figs 1E](#) and [EV1B-E](#)). Furthermore, quantification
153 of differential transcript usage via IsoformSwitchAnalyzeR (*Vitting-Seerup & Sandelin*, 2019)
154 could neither detect any differences in the global isoform fraction distribution, nor an
155 accumulation of PTC-containing transcripts ([Fig EV1F](#)). Collectively, these analyses indicated
156 that UPF3A overexpression in HEK 293 cells does not negatively affect gene expression in
157 general or NMD in particular.

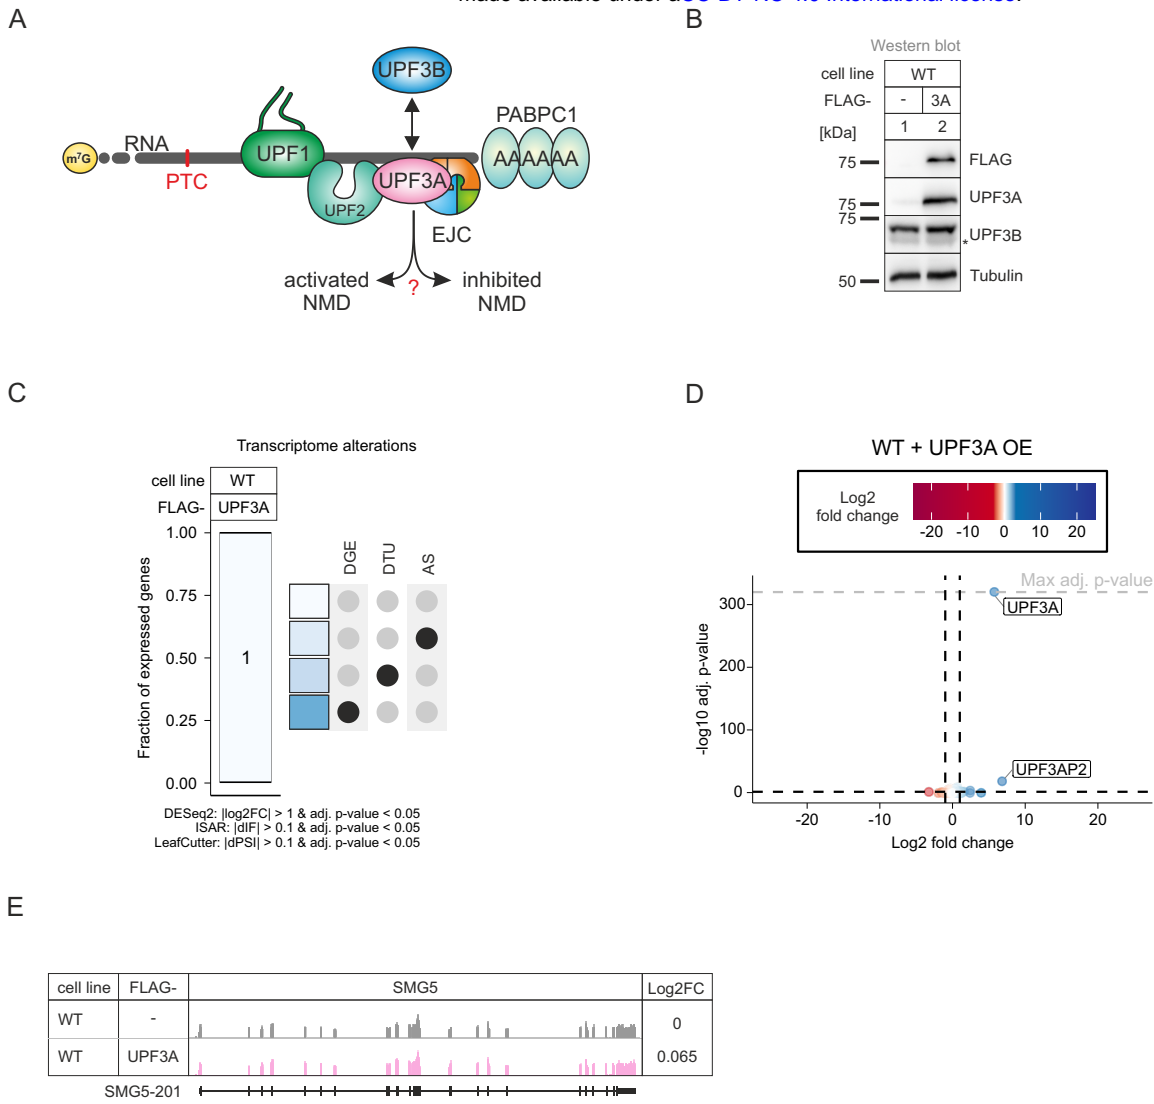

Figure 1 - UPF3A overexpression does not affect NMD

A Schematic representation of the bridge between UPF1 and the EJC during NMD. Binding of UPF3A instead of the stronger bound UPF3B is discussed to either activate or inhibit NMD.

B Western blot analyses after induced expression of FLAG-tagged UPF3A in WT HEK 293 cells. Tubulin serves as control.

C Fraction of expressed genes (genes with non-zero counts in DESeq2) were calculated which exhibit individual or combinations of differential gene expression (DGE), differential transcript usage (DTU) and/or alternative splicing (AS) events in WT cells overexpressing UPF3A using the respective computational analysis (cutoffs are indicated). AS and DTU events were collapsed on the gene level. For DGE, p-values were calculated by DESeq2 using a two-sided Wald test and corrected for multiple testing using the Benjamini-Hochberg method. For DTU, p-values were calculated by IsoformSwitchAnalyzeR (ISAR) using a DEXSeq-based test and corrected for multiple testing using the Benjamini-Hochberg method. For AS, p-values were calculated by LeafCutter using an asymptotic Chi-squared distribution and corrected for multiple testing using the Benjamini-Hochberg method.

D Volcano plot showing the differential gene expression analyses from the RNA-Seq dataset of WT cells overexpressing UPF3A. The log₂ fold change is plotted against the -log₁₀ adjusted p-value (adj. p-value). P-values were calculated by DESeq2 using a two-sided Wald test and corrected for multiple testing using the Benjamini-Hochberg method. OE = overexpression.

E Read coverage of SMG5 from WT HEK 293 RNA-seq data with or without induced UPF3A overexpression shown as Integrative Genomics Viewer (IGV) snapshot. Differential gene expression (from DESeq2) is indicated as Log₂ fold change (Log₂FC) on the right. Schematic representation of the protein coding transcript below.

159 Next, we approached the question of UPF3A function in the opposite way by generating
160 UPF3A knockout (KO) HEK 293 cell lines. Using CRISPR-Cas9 genome editing we isolated
161 three clones that lacked the UPF3A-specific band on the Western blot even after
162 downregulation of UPF3B (Fig 2A). Two clones (14 and 20) were characterized in detail.

163 In both cell lines, the UPF3A genomic locus contained insertions and/or deletions causing
164 frame-shifts and eventually PTCs (Figs EV2A-C). To gain a first impression of the NMD activity
165 in the UPF3A KO cells, the transcript levels of three known exemplary endogenous NMD
166 targets, RSRC2, SRSF2 and ZFAS1 were determined by qPCR (Boehm *et al.*, 2021; Lykke-
167 Andersen *et al.*, 2014; Sureau *et al.*, 2001). WT HEK 293 cells treated with SMG6 and SMG7
168 siRNAs were used as a positive control for severe NMD inhibition (Fig 2B)(Boehm *et al.*, 2021).
169 While the absence of UPF3A did not result in abundance changes of SRSF2 and RSRC2
170 NMD-sensitive isoforms (mean log₂FC between -0.44 and 0.79), ZFAS1 mRNA levels were
171 slightly decreased in the UPF3A KO cells compared to WT cells (mean log₂FC -0.42 and -1.01
172 for UPF3A KO clones 14 and 20, respectively; Fig 2B). However, this effect was not rescued
173 by the (over)expression of transgenic UPF3A, indicating that it is not caused by the lack of
174 UPF3A but rather represents random variations in gene expression or clonal effects (Figs
175 EV2D-E). To get a complete overview of the effects of the UPF3A KO, we performed RNA-seq
176 of two UPF3A KO cell lines with or without an additional UPF3B knockdown (KD; Fig EV2F
177 and Datasets EV1-EV3). Initially, we focused on the UPF3A KO cell lines without KDs, for
178 which the global transcriptome analysis revealed that about 4-9 % of the expressed genes are
179 altered (Figs 2C-E). The observation that in the absence of UPF3A more genes were
180 downregulated than upregulated (879 vs. 676) could be an indicator for UPF3A NMD inhibiting
181 properties (Fig 2F). However, the majority of genes with altered expression were clone specific
182 and only 110 genes showed downregulation in both UPF3A KO cell lines (Fig 2F). Investigation
183 of selected targets that were significantly up- or downregulated in both clones revealed that
184 the changes were not rescued after UPF3A overexpression, suggesting that they are UPF3A-
185 independent (Figs EV2D-E). Another indication that UPF3A depletion does not generally affect
186 NMD efficiency came from the DTU analysis.

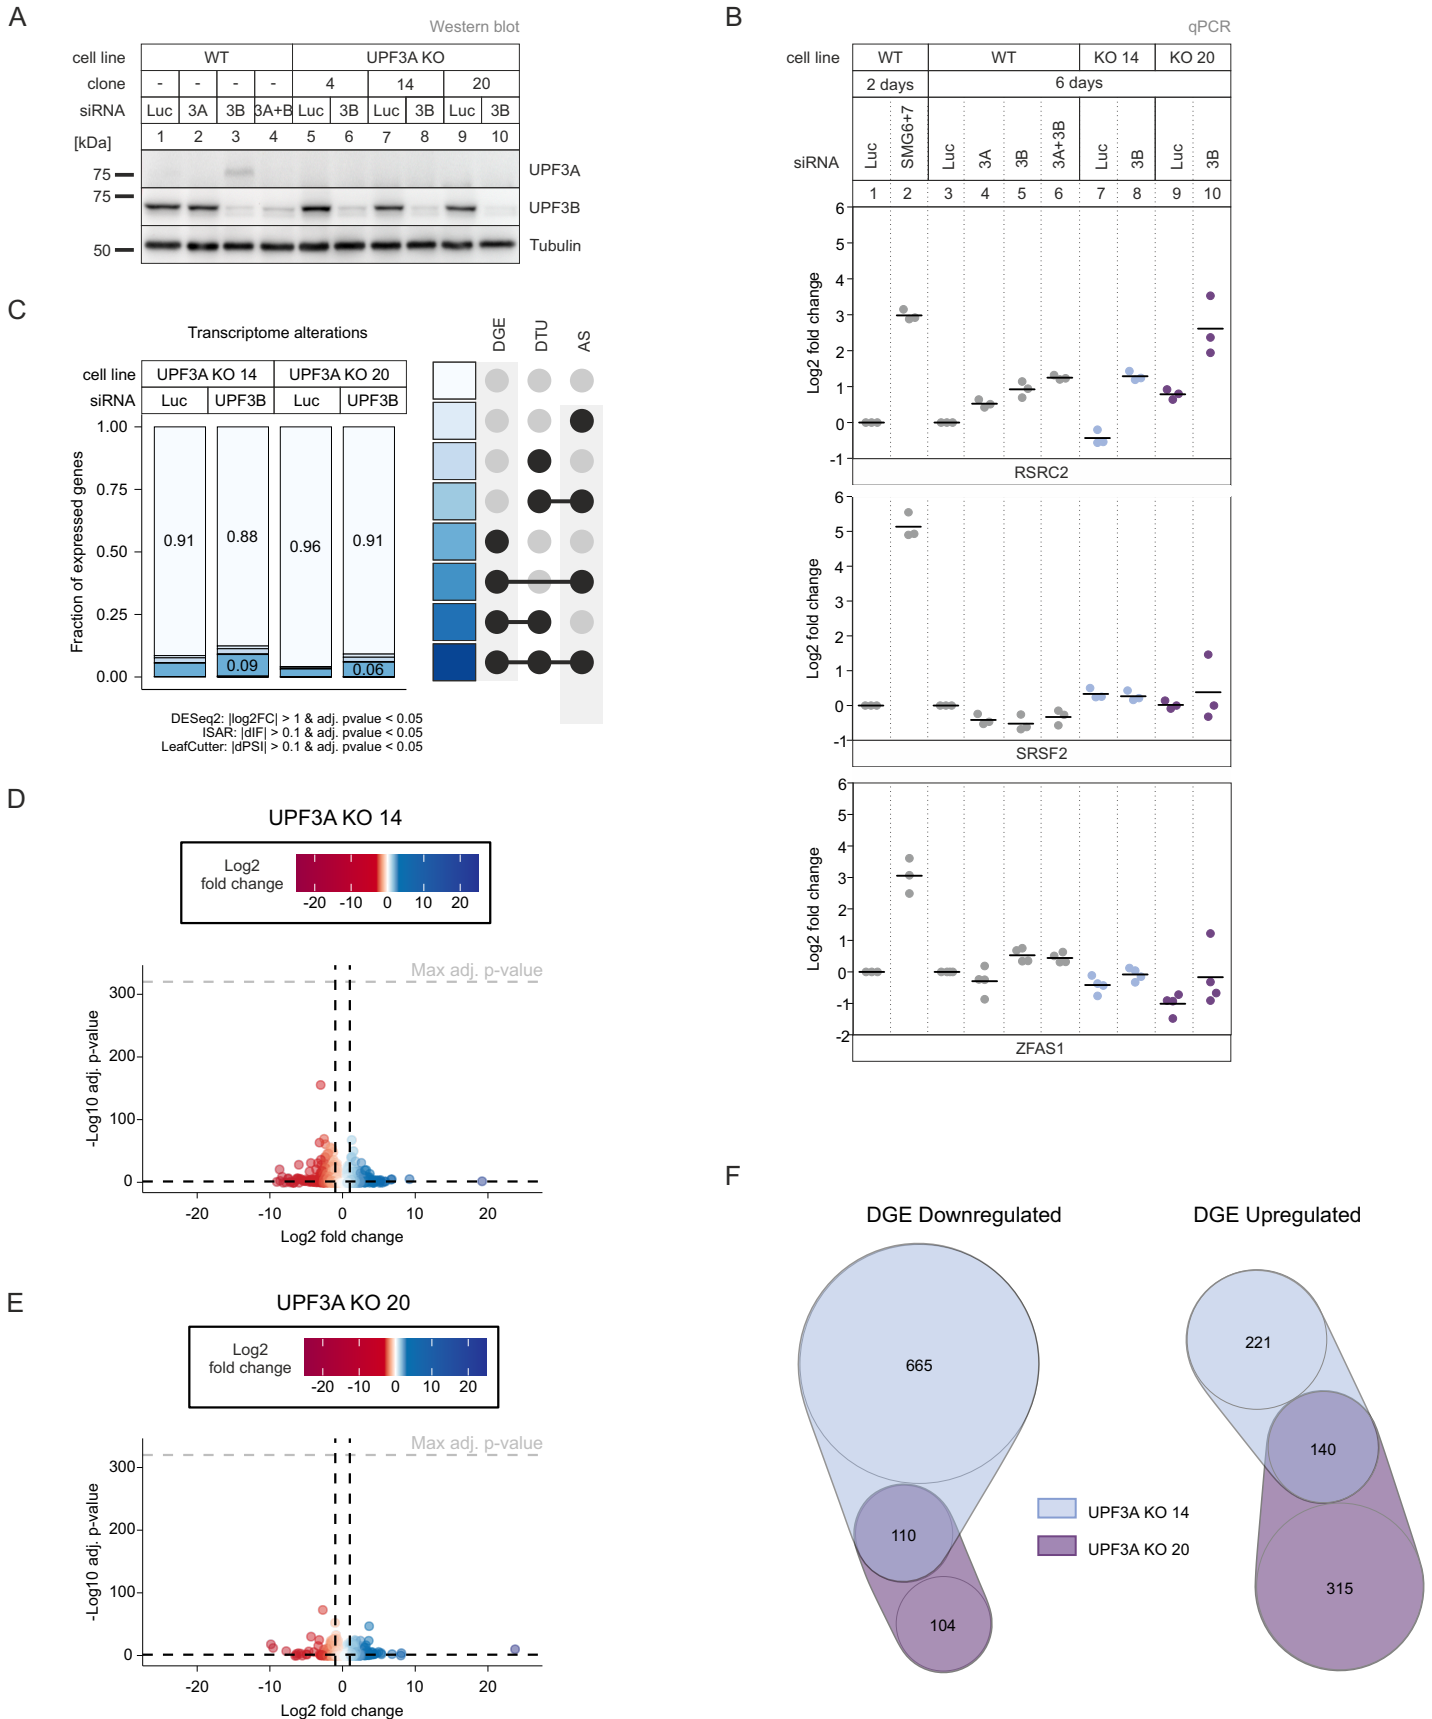

Figure 2 - UPF3A KOs show light NMD-independent transcriptome alterations

A Western blot analysis of WT and UPF3A KO cells (clones 4, 14 and 20) with the indicated siRNA treatments. UPF3A and UPF3B protein levels were detected, Tubulin serves as control.

B Quantitative RT-PCR of the indicated cell lines treated with the indicated siRNA treatments for 2 or 6 days. For RSRC2 and SRSF2 the ratio of NMD isoform to canonical isoform was calculated. ZFAS1 expression was normalized to C1orf43 reference. Data points and means are plotted as Log₂ fold change (n=3 for RSRC2 and SRSF2, n=4 for ZFAS1).

C Fraction of expressed genes (genes with non-zero counts in DESeq2) were calculated which exhibit individual or combinations of differential gene expression (DGE), differential transcript usage (DTU) and/or alternative splicing (AS) events in the indicated conditions using the respective computational analysis (cutoffs are indicated). AS and DTU events were collapsed on the gene level. For DGE, p-values were calculated by DESeq2 using a two-sided Wald test and corrected for multiple testing using the Benjamini-Hochberg method. For DTU, p-values were calculated by IsoformSwitchAnalyzeR using a DEXSeq-based test and corrected for multiple testing using the Benjamini-Hochberg method. For AS, p-values were calculated by LeafCutter using an asymptotic Chi-squared distribution and corrected for multiple testing using the Benjamini-Hochberg method.

D,E Volcano plots showing the differential gene expression analyses from the indicated RNA-Seq datasets (D UPF3A KO clone 14, E UPF3A KO clone 20). The log₂ fold change is plotted against the -log₁₀ adjusted p-value (padj). P-values were calculated by DESeq2 using a two-sided Wald test and corrected for multiple testing using the Benjamini-Hochberg method.

F nVenn Diagram showing the overlap of up- or downregulated genes in the UPF3A KO cell lines 14 and 20. Log₂ fold change < 1 (downregulated) or > 1 (upregulated) and adjusted p-value (padj) < 0.05 . DGE = Differential Gene Expression.

188 Although clone 14 showed a minor downregulation of PTC-containing transcripts, which could
189 indicate more active NMD, this effect was not reproducible in the second clone (Fig EV2G). In
190 view of and in combination with the results shown in Fig 1, this strongly suggests that neither
191 the overexpression nor the depletion of UPF3A substantially alters (negatively or positively)
192 the efficiency of NMD. In conclusion, our data argue against a role for UPF3A as a general
193 negative NMD regulator in human cell lines.

194 **NMD is functional in the absence of UPF3B**

195 Next, we investigated the RNA-seq data of UPF3B knockdowns in the UPF3A KO cells
196 (Datasets EV1-EV3). We observed that this combination resulted in more transcriptome
197 alterations and an increase of PTC-containing isoforms (Figs 2B-C, EV2H and I). Although the
198 UPF3B KD alone could be in principle responsible for this effect, the results could also be an
199 indicator for redundant functions of the two UPF3 paralogs. To explore this hypothesis, we
200 decided to generate UPF3B KO cell lines. Western blot analysis demonstrated that a UPF3B
201 KD is less efficient in reducing the produced protein than the UPF3B KO in the two clones
202 designated as 90 and 91 (Figs 3A and EV3A-B). In addition, we observed a strong upregulation
203 of UPF3A after depletion (KO) or reduction (KD) of UPF3B, as described before (Chan *et al.*,
204 2009). In the absence of UPF3B no changes in the expression of the respective NMD-sensitive
205 isoforms of the NMD-targets RSRC2 and SRSF2 was observed (Fig 3B). This indicates that
206 either UPF3B is not essential for NMD or that another protein is able to compensate for its
207 loss. The most obvious candidate for this function is its own paralog UPF3A, which was also
208 suggested previously to functionally replace UPF3B in NMD. Indeed, knocking down UPF3A
209 in the UPF3B KO cells resulted in the increase of NMD-sensitive RSRC2 and SRSF2 isoforms
210 (Fig 3B). Of note, the combination of the UPF3B KO with UPF3A KD showed stronger effects
211 than the previously analyzed UPF3A KO plus UPF3B KD. This is probably caused by the lower
212 KD efficiency of the UPF3B siRNAs which can be observed by comparing the respective
213 protein levels (Fig 2A vs. Fig 3A). We suspect that the remaining UPF3B levels after siRNA-
214 mediated UPF3B KD still support NMD.

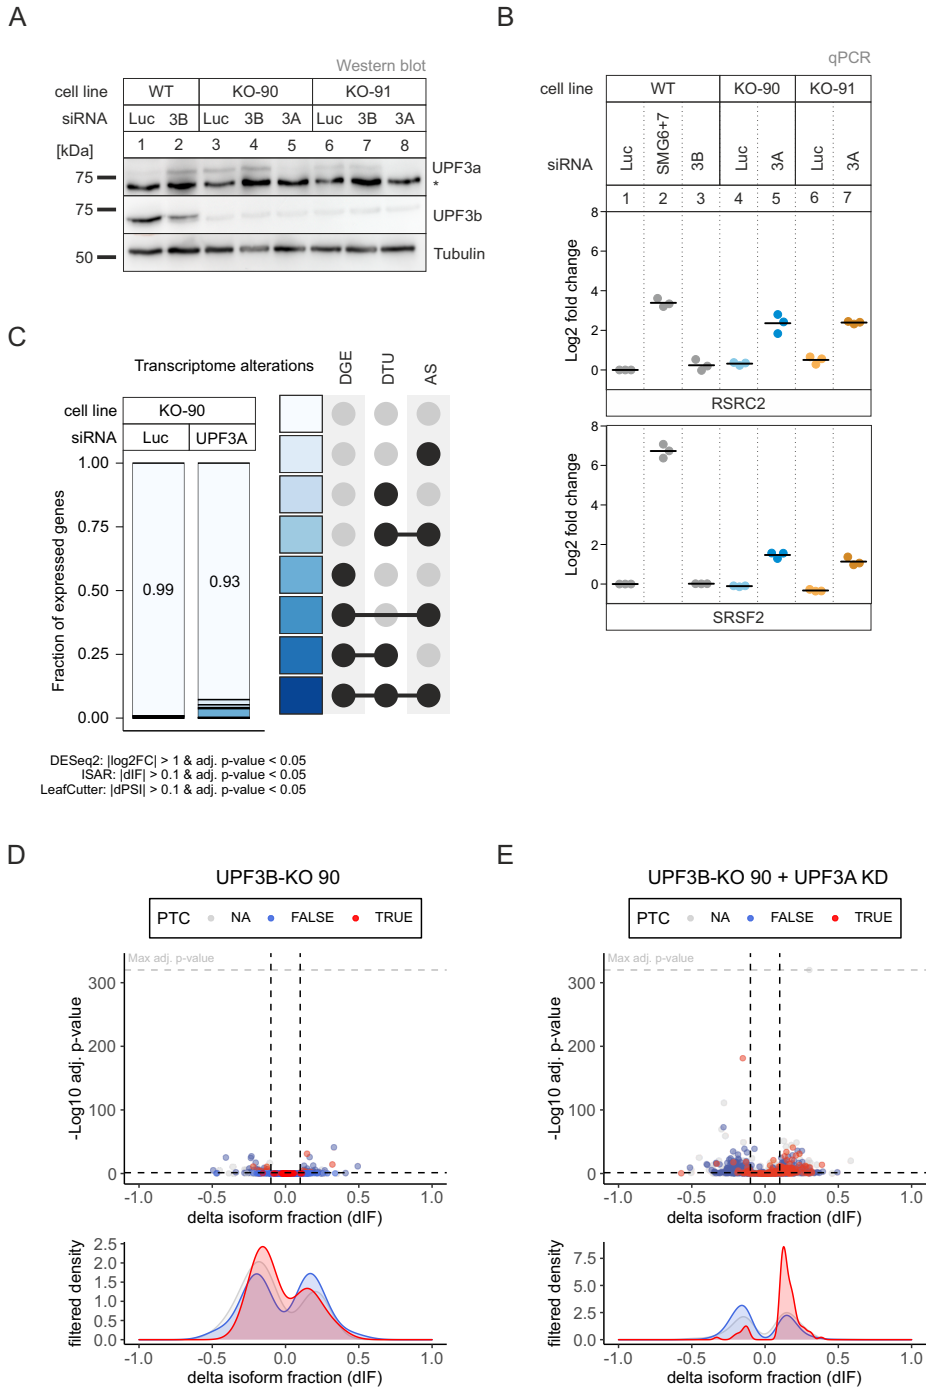

Figure 3 - Loss of UPF3B does not affect NMD efficiency, only in combination with KD of UPF3A

A Western blot analysis of WT and UPF3B KO cells (clones 90 and 91) combined with the indicated knockdowns. UPF3A and UPF3B (AK-141) protein levels were detected, Tubulin serves as control.

B Quantitative RT-PCR of the indicated cell lines with the indicated knockdowns. For RSRC2 and SRSF2 the ratio of NMD isoform to canonical isoforms was calculated. Data points and means are plotted as Log₂ fold change (n=3).

C Fraction of expressed genes (genes with non-zero counts in DESeq2) were calculated which exhibit individual or combinations of differential gene expression (DGE), differential transcript usage (DTU) and/or alternative splicing (AS) events in the indicated conditions using the respective computational analysis (cutoffs are indicated). AS and DTU events were collapsed on the gene level. For DGE, p-values were calculated by DESeq2 using a two-sided Wald test and corrected for multiple testing using the Benjamini-Hochberg method. For DTU, p-values were calculated by IsoformSwitchAnalyzeR using a DEXSeq-based test and corrected for multiple testing using the Benjamini-Hochberg method. For AS, p-values were calculated by LeafCutter using an asymptotic Chi-squared distribution and corrected for multiple testing using the Benjamini-Hochberg method.

D,E Volcano plots showing the differential transcript usage (via IsoformSwitchAnalyzeR) in various RNA-Seq data. Isoforms containing GENCODE (release 33) annotated PTC (red, TRUE), regular stop codons (blue, FALSE) or having no annotated open reading frame (grey, NA) are indicated. The change in isoform fraction (dIF) is plotted against the -log₁₀ adjusted p-value (adj. p-value). Density plots show the distribution of filtered isoforms in respect to the dIF, cutoffs were $|dIF| > 0.1$ and adj. p-value < 0.05. P-values were calculated by IsoformSwitchAnalyzeR using a DEXSeq-based test and corrected for multiple testing using the Benjamini-Hochberg method.

216 To gain more transcriptome-wide information, we performed RNA-seq of the UPF3B KO clone
217 90, with and without UPF3A siRNA treatment (Fig EV3C and Datasets EV1-EV3). The global
218 effects detected in the RNA-seq data correlated well with the NMD inhibition seen for single
219 targets (Figs 3C and EV3D-G). Analysis of the differential transcript usage revealed an
220 upregulation of transcripts annotated with a PTC only in the UPF3B KO cells with additionally
221 downregulated UPF3A (Figs 3D and E). This increase of NMD-sensitive transcripts could not
222 be observed in the plain UPF3B KO cells with UPF3A naturally upregulated. All together this
223 data strongly suggested at least partial redundancy of UPF3A and UPF3B, since KO of only
224 one paralog was irrelevant for NMD functionality. Furthermore, we were able to show that also
225 in the absence of UPF3B an overexpression of UPF3A has no negative effects on NMD
226 efficiency, supporting the previous conclusion of UPF3A not being a negative NMD regulator
227 (Figs EV3H and I).

228 **Stronger NMD impairment in UPF3A-UPF3B double KO cells**

229 Considering that UPF3A and UPF3B seemingly carry out redundant functions, we decided to
230 create a cell line completely lacking both paralogs and aimed to generate UPF3A-UPF3B
231 double KO cells (UPF3 dKO). These cells should show stronger effects than the combination
232 of a KO and a KD, since residual amounts of protein were typically still detected after siRNA
233 treatment. Using the UPF3B-KO clone 90 as parental cell line, two potential UPF3 dKO clones
234 1 and 2 were generated (Fig 4A), which differed in the guide RNAs used to target exon 1 of
235 UPF3A. We confirmed that both cell lines contained frame shift-inducing insertions/deletions
236 at the respective positions in the UPF3A gene (Figs 4B, EV4A and B). We first explored by
237 qPCR how strongly the dKO affected NMD (Fig 4C). For all three tested genes, the expression
238 of the NMD-sensitive isoform was further increased compared to the previously used
239 combination of UPF3B KO with additional UPF3A KD. Of note, the NMD inhibitory effect
240 observed in the dKOs became more pronounced after UPF3B siRNA transfection, suggesting
241 that low levels of residual UPF3B protein were still present in the dKO cells (Fig EV4C).

Figure 4 - KO of both UPF3 paralogs results in strongly impaired NMD

A Western blot analysis of WT, UPF3B KO and UPF3A-UPF3B doubleKO cells (clones 1 and 2). UPF3A and UPF3B protein levels were detected, Tubulin serves as control.

B Schematic depiction of the insertion/deletion in the UPF3A open reading frame resulting in the additional UPF3A KO in the UPF3B KO clone 90 generating UPF3 dKO clones.

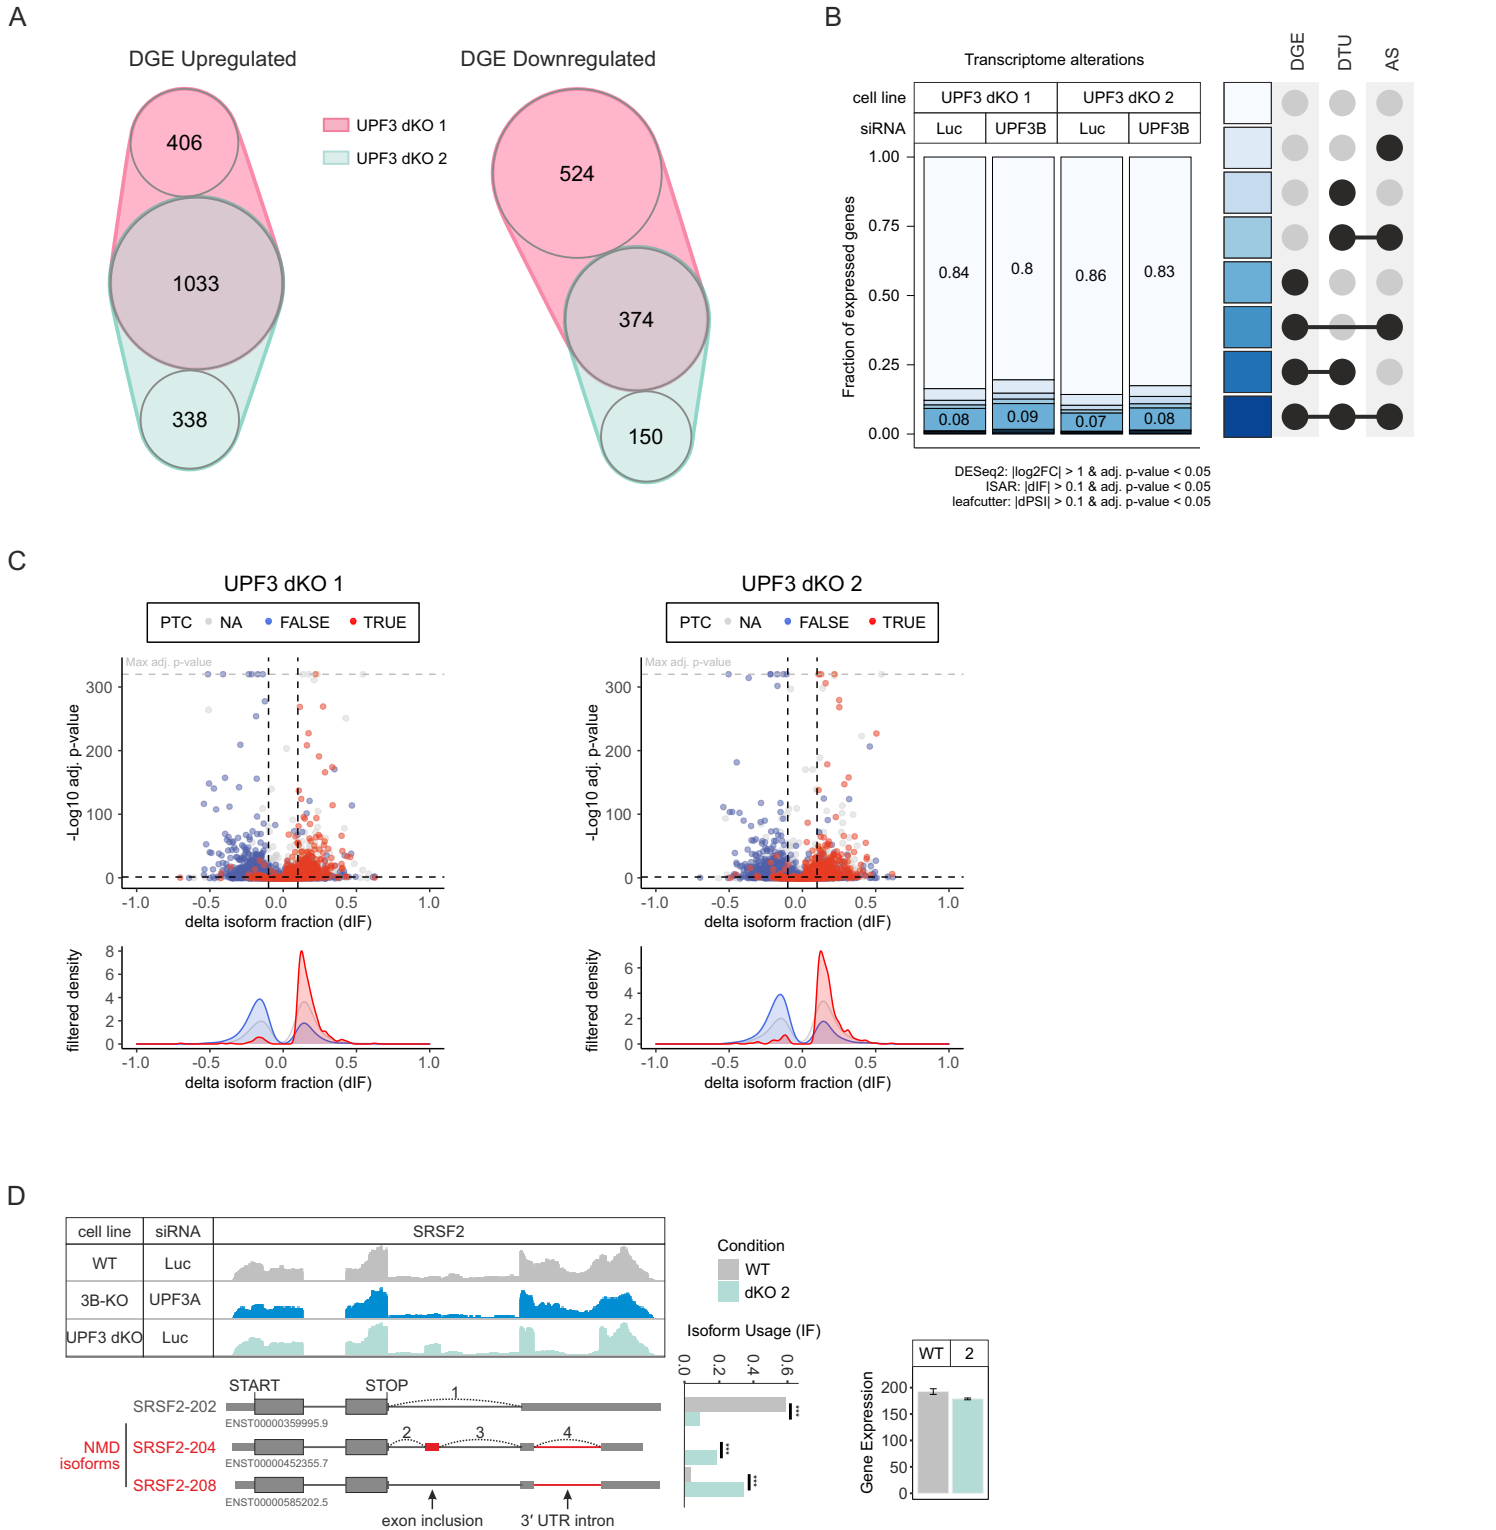

C Quantitative RT-PCR of the indicated samples with the indicated KDs. For RSRC2 and SRSF2 the ratio of NMD isoform to canonical isoform was calculated. ZFAS1 expression was normalized to C1orf43 reference. Data points and means are plotted as Log₂ fold change (n=3).

D Schematic overview of the globin reporter constructs and their functional elements.

E Northern blot analysis of globin reporter and xrFrag. Ethidium bromide stained 28S and 18S rRNAs are shown as controls. Quantification results are shown as data points and mean (n=3).

243 The expression levels of endogenous NMD substrates could be influenced by transcription
244 rates or other indirect effects, which could lead to over- or underestimating NMD inhibition.
245 Therefore, we investigated the NMD efficiency in the dKO cells using the well-established β -
246 globin NMD reporter. To this end, we stably integrated β -globin WT or PTC39 constructs in
247 WT and UPF3 dKO cells (Fig 4D). These reporters also contained XRN1-resistant sequences
248 (xrRNAs) in their 3' UTRs, which allowed us to analyze not only the degradation of the full-
249 length reporter mRNA but also to quantify decay intermediates (called xrFrag) (Boehm *et al.*,
250 2016; Voigt *et al.*, 2019). The PTC39 mRNA was efficiently degraded and a strong xrFrag
251 observed in WT cells, whereas in dKO cells the PTC39 reporter accumulated to high levels
252 (72% compared to the WT mRNA), which was accompanied by a decrease in the amount of
253 xrFrag. (Fig 4E, lane 2 vs. lane 4). In line with the previous observations, this result indicated
254 a strong decrease of NMD activity upon the KO of both UPF3 paralogs using a robust NMD
255 reporter pair expressed independently of endogenous NMD substrates, supporting the
256 functional redundancy of UPF3A and UPF3B in NMD.

257 To establish transcriptome-wide insights into UPF3A and UPF3B function, we carried out RNA-
258 seq for both dKO clones, which was combined with and without UPF3B KD treatment to
259 eliminate as many of the potentially present remaining UPF3B proteins (Fig EV5A and
260 Datasets EV1-EV3). Differential gene expression analysis showed that nearly three times as
261 many genes were upregulated than downregulated in both dKO cells (Figs 5A and EV5B). This
262 is consistent with the redundant role of UPF3B and UPF3A as supporting NMD factors. The
263 considerable overlap between both clones also suggests that we identified high-confidence
264 UPF3 targets. Furthermore, 890 of these gene were also significantly upregulated in previously
265 generated SMG7 KO plus SMG6 KD data (Fig EV5C, ref data: (Boehm *et al.*, 2021)) indicating
266 that these are universal NMD-targets and not specific to a certain branch of the NMD pathway.
267 In addition to DGE, subsets of the expressed genes showed changes in alternative splicing
268 or/and differential transcript usage (Fig 5B). In total, 14-16 % of the global transcriptome
269 showed single or combined changes (DGE, DTU and/or AS) and up to 20% when the cells
270 were treated with an additional UPF3B KD.

272 In agreement with NMD inhibition in the dKOs, we saw that many transcripts containing a PTC
273 were up-regulated, while the corresponding transcripts without a PTC were down-regulated.
274 (Figs 5C and EV5D). Under these conditions, the IGV snapshot of the NMD-target SRSF2
275 showed NMD-inducing exon inclusion and 3' UTR splicing events, which were not visible in
276 combined UPF3B KO/UPF3A KD cells (Fig 5D). Collectively, the RNA-seq data support the
277 previously observed strong NMD inhibition in response to the complete absence of both UPF3
278 paralogs and hence their proposed redundancy.

279 **UPF3A supports NMD independent of a bridge function**

280 Next, we aimed to analyze whether the severe effects in the dKOs are at least partly due to
281 the loss of a protein-protein interaction bridge between UPF2 and the EJC, while the presence
282 of UPF3A in the UPF3B KOs preserved this function ensuring NMD functionality. Therefore,
283 we expressed FLAG-tagged UPF2 in WT, UPF3B KO and UPF3A-UPF3B dKO cells and
284 analyzed the UPF2 interactome using mass spectrometry (Dataset EV4). Consistent with the
285 previously described interaction partners, we found many NMD factors as well as EJC proteins
286 in the UPF2 interactome in WT cells (Fig 6A). Contrary to our expectation, the three EJC core
287 components (EIF4A3, RBM8A, MAGOHB) barely co-precipitated with UPF2 in the absence of
288 UPF3B (compared to control: log₂ FC = 0.58, 0.63 and 0.74, respectively; Fig 6B) and were
289 therefore strongly decreased in comparison to the WT cells (Fig EV6A). Hence, the UPF2-
290 bound UPF3A was unable to establish a stable interaction with the EJC. Surprisingly, in the
291 UPF3B KO cells the EJC-associated CASC3 still showed relatively high levels of co-
292 precipitation (log₂ FC = 4.42), which therefore appears to be independent of the interaction
293 with the other EJC components. In the dKOs all interactions with EJC proteins including
294 CASC3 were completely lost (Figs 6C and EV6B). The latter was also observed in a
295 comparable approach employing stable isotope labeling with amino acids in cell culture
296 (SILAC) to analyze the UPF2 interactome in the WT and dKO cells (Dataset EV5). All EJC
297 core components that were highly co-precipitated in WT cells were lost in the absence of both
298 UPF3 paralogs (Figs EV6C-E).

300 **Partially redundant functions of UPF3B domains are required for NMD**

301 With regard to the surprising observation that UPF3A apparently elicits NMD without
302 interacting with the EJC, we aimed to investigate the molecular features required by UPF3 to
303 support NMD via rescue experiments. In principle, the UPF3 dKO cells represent an ideal
304 system for this approach. However, apart from the residual amounts of UPF3B that were still
305 expressed, we noticed that the UPF3 dKOs were able to upregulate the expression of a
306 shortened UPF3B variant after long-term cultivation.

307 Since this phenomenon did not occur in the single UPF3B KOs, we generated stable UPF3B
308 KO cell lines expressing various inducible UPF3B constructs with individual or combined
309 binding site mutations (Figs 6D and E and EV6F). Transfection of these cells with UPF3A
310 siRNAs resulted in the robust depletion of UPF3 for the analysis of the rescue activities of
311 individual UPF3B variants. Considering the established role of UPF3B as a bridge between
312 UPF2 and the EJC, which we validated in the mass spec analysis, it was surprising to see that
313 disruption of either of these interactions did not affect UPF3B's rescue capacity (Fig 6F, lane
314 3 vs. lanes 4 and 5). This is partially consistent with the observed functional NMD in UPF3B
315 KOs, despite the apparent inability of UPF3A to form a bridge between UPF2 and the EJC
316 (Figs 3C and 6B). However, mutating both UPF3B binding sites (disrupting UPF2 and EJC
317 binding) largely inactivated the NMD-related function of UPF3B.

318 It was recently reported that EJC-bound or free UPF3B can interact with the eukaryotic release
319 factor 3 (eRF3) via the so far uncharacterized middle domain (aa 147-256) (Neu-Yilik *et al.*,
320 2017). With this interaction and binding of the terminating ribosome, UPF3B can delay
321 translation termination, which defines aberrant termination events and triggers NMD (Amrani
322 *et al.*, 2004; Neu-Yilik *et al.*, 2017; Peixeiro *et al.*, 2012). To investigate the impact of this
323 interaction on NMD, we created UPF3B variants lacking that specific middle domain or
324 combined the deletion with the previously used interaction mutations (Fig 6D and E). We
325 observed a similar pattern as the UPF3B mutants examined in the previous experiment: when
326 only the middle domain was deleted, UPF3B was able to rescue NMD comparable to the WT

327 protein (Fig 6F lane 7). In combination with a mutation in the UPF2- or the EJC binding site its
328 function in NMD was severely impaired (lanes 8 and 9). This suggests that if the classic bridge
329 formation is inhibited by removing either of the interaction sites, UPF3B relied on the function
330 carried out by the uncharacterized middle domain.

331 As further support for the NMD promoting effect of UPF3A on NMD, we performed a rescue
332 experiment in the above used UPF3B KO UPF3A KD cells (Figs 7A and B). Expression of the
333 siRNA insensitive UPF3A construct did not only restore NMD functionality, it was even more
334 efficient than the UPF3B construct (Fig 7C lane 3 vs. lane 5), underlining our previous
335 statement: UPF3A supports and elicits NMD comparably to its paralog UPF3B.

336 Also comparable to UPF3B, UPF3A has a second naturally occurring isoform but instead of
337 skipping exon 8 (like UPF3B) it excludes its fourth exon. This isoform is transcribed in
338 approximately one third of the cases (Fig EV6G) in WT HEK 293 cells but cannot be detected
339 on protein levels. We were interested, whether this isoform was as potent to elicit NMD as the
340 full-length construct. Expression of the exon 4 UPF3A deletion construct in the UPF3 depleted
341 cells showed no rescue (Fig 7C lane 4). Hence, exon 4 must encode for an essential region
342 required for the bridge-independent function of UPF3A.

343 In view of these observations and the close proximity of exon 4 (124-157) to the middle domain
344 (147-256), we decided to investigate which effect the deletion of the homologous exon 4 in the
345 paralog UPF3B has. The UPF3B $\Delta e4$ construct behaved like the corresponding UPF3A
346 construct and showed no NMD rescue activity (lane 6). However, the expression of the N-
347 terminus of UPF3B was able to restore NMD comparably to the WT protein (lane 7). This is
348 consistent with all our previous findings, since the first 279 amino acids contain the UPF2
349 binding site as well as the middle domain, which was shown to be sufficient to elicit NMD (Fig
350 6F lane 5). Due to the fact that the C-terminus contains only one interaction site and lacks exon
351 4, its incapability to rescue NMD is in line with our previous experiments. Overall, our results
352 identify exon 4 of UPF3 as a previously unnoticed region that is essential for its function in
353 NMD.

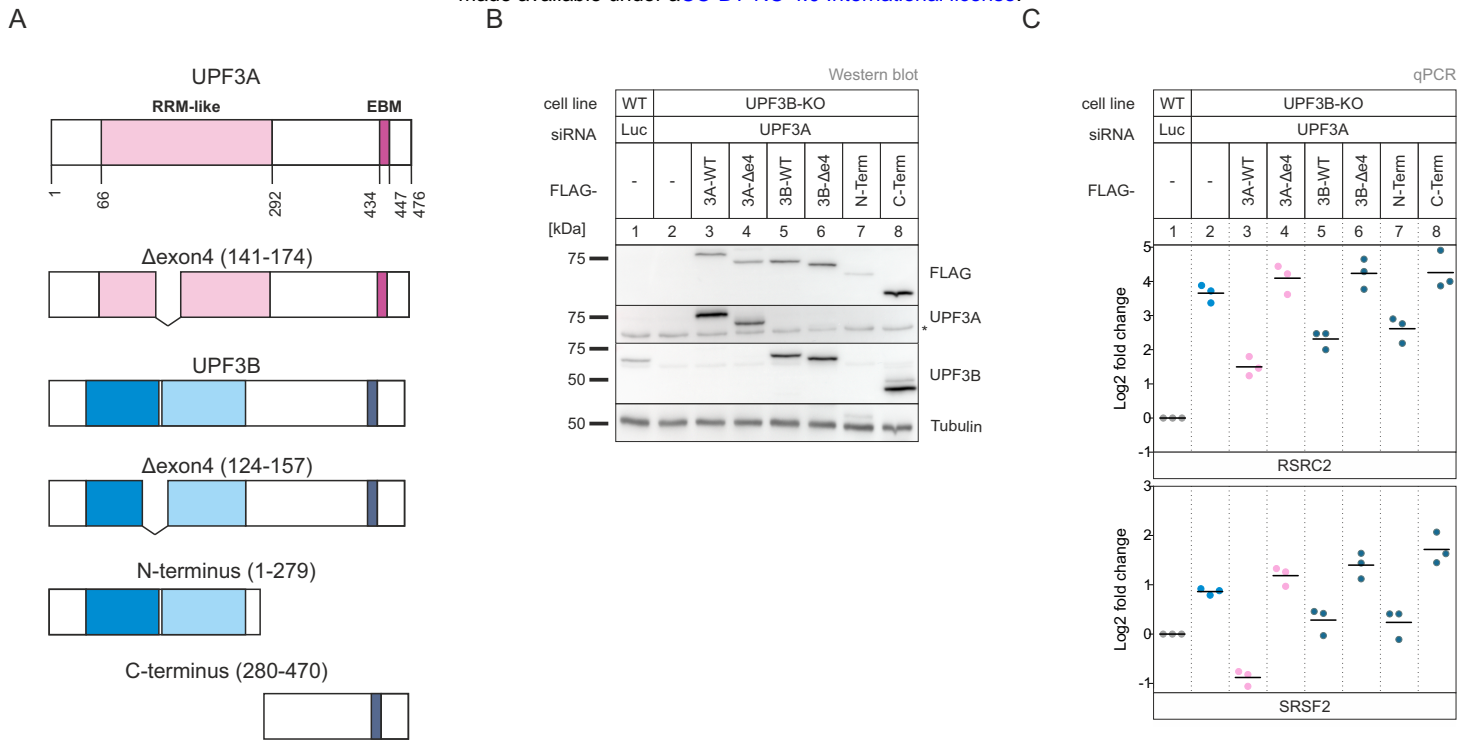

Figure 7 - WT UPF3A can rescue NMD in full extent. Deletion on exon 4 disrupts functionality in both paralogs.

A Schematic representation of the UPF3A and UPF3B protein domains. Below are the respective mutated rescue constructs.

B Western blot analysis of WT and UPF3B KO clone 90 with Luciferase and UPF3A KDs respectively. Monitored expression of the FLAG-tagged UPF3A and UPF3B rescue construct shown in (A). Rescue construct protein levels were detected with anti-FLAG, anti-UPF3A and anti-UPF3B (AK-141) antibodies. Tubulin serves as control.

C Quantitative RT-PCR of the samples from (B). For RSRC2 and SRSF2 the ratio of NMD isoform to canonical isoform was calculated. Data points and means are plotted as log₂ fold change (n=3).

355 **Discussion**

356 Methodological advances - be it improved analytics or novel experimental approaches - can
357 help to find new answers to old biological problems. Equipped with powerful new molecular
358 biology methods, we set out to answer the question which functions the two UPF3 paralogs
359 carry out in human cells. Since the initial description of mammalian UPF3A and UPF3B (Lykke-
360 Andersen *et al.*, 2000; Serin *et al.*, 2001), many researchers have been engaged in determining
361 the function and work distribution of these two proteins in NMD. It became clear relatively early
362 that UPF3A and UPF3B can both interact with UPF2 as well as the EJC and activate NMD
363 (Gehring *et al.*, 2003; Kim *et al.*, 2001; Lykke-Andersen *et al.*, 2000; Serin *et al.*, 2001). But
364 significant differences in these interactions and the amounts of UPF3A and UPF3B proteins
365 were also found, leading to the hypothesis that UPF3B is the central player and UPF3A more
366 its backup (Chan *et al.*, 2009; Kunz *et al.*, 2006). The investigations were further intensified
367 upon the discovery that mutations in the human UPF3B gene lead to various forms of mental
368 disorder (Nguyen *et al.*, 2014). Disease severity seems to be dictated by the amount of UPF3A
369 present, suggesting again a compensatory mechanism and redundant functions of UPF3B and
370 UPF3A (Nguyen *et al.*, 2012).

371 Later, it was reported that in mouse cells UPF3B is an NMD activator and UPF3A is an NMD
372 inhibitor (Shum *et al.*, 2016). Accordingly, removal of UPF3A resulted in enhanced NMD,
373 whereas removal of UPF3B inhibited NMD. Recently, another function of UPF3B was
374 discovered, namely that it is involved in different phases of translation termination (Neu-Yilik
375 *et al.*, 2017). UPF3B not only interacts with release factors, but also slows down translation
376 termination and promotes dissociation of post-termination ribosomal complexes. Whether
377 these functions of UPF3B in translation termination are related to its function in NMD has not
378 been clarified to date.

379 Although our results cannot fully answer this last question, we have more or less definite
380 answers for the functions of the two proteins UPF3A and UPF3B in NMD. All our data support
381 the notion that the presence of UPF3B or UPF3A is sufficient to maintain NMD activity in

382 human cells. First, we see at most a weak inhibition of NMD in our HEK 293 UPF3B KO cells.
383 However, this does not necessarily mean that all cell types display full NMD activity after a KO
384 of UPF3B. Instead, it is conceivable that HEK 293 cells are just particularly robust against the
385 UPF3B depletion or particularly efficient at the compensatory upregulation of UPF3A. Likewise,
386 we see no NMD inhibition in cells overexpressing UPF3A or NMD “boosting” in UPF3A KO
387 cells. Only when we deplete in UPF3A or UPF3B KO cell lines the respective other protein by
388 RNAi or genomic KO, NMD efficiency substantially decreases. It should be noted that the
389 effects of a KO on NMD activity are typically stronger than those of a KD, which is consistent
390 with our earlier observations (Boehm *et al.*, 2021; Gerbracht *et al.*, 2020). Although our data
391 clearly argue against an NMD-inhibitory function of UPF3A, experimental differences exist
392 between our work and the work describing the NMD inhibition by UPF3A. While we have used
393 human HEK293 cells, the results of Shum *et al.* were obtained in P19 mouse cells and mouse
394 embryonic fibroblasts (MEFs). Both, the different organisms and the different types of cells
395 could have influenced the results. Interestingly, in a parallel manuscript, Yi *et al.* find that
396 mouse UPF3A can rescue NMD in human HCT116 UPF3A-UPF3B dKO cells (Yi *et al.*, 2021).
397 Although these results were obtained in a heterologous context, mouse UPF3A does not
398 appear to be a general NMD inhibitor.

399 The different KO cells that we have generated in the course of this project enabled us to
400 conduct experiments that went beyond investigating UPF3-dependent NMD substrates in
401 human cells. Specifically, we were able to study the composition of NMD complexes without
402 UPF3B or both UPF3 proteins and to carry out rescue experiments with different UPF3A and
403 UPF3B protein variants. Not entirely unexpected, we observed that in the absence of UPF3A
404 and UPF3B, the interaction between UPF2 and the EJC is lost. This bridging by UPF3 between
405 UPF2-containing NMD complexes and the EJC was previously considered to be essential for
406 NMD. However, two observations argue against UPF3 being mainly a bridging protein. First,
407 UPF3B mutants that cannot interact with either the EJC or UPF2 fully rescue NMD. Only when
408 both interaction sites were mutated, UPF3 lost its NMD function. This indicates that the
409 interaction with one of the two interaction partners is sufficient to maintain NMD. Second, we

410 observed that not only in UPF3 double-KO cells, but also in UPF3B KO cells, the bridge
411 between UPF2 and the EJC was lost. Although quite surprising at first glance, this is in good
412 agreement with previous results showing that the interaction between the EJC and UPF3A is
413 substantially weaker than that between the EJC and UPF3B (Kunz *et al.*, 2006). Indeed, earlier
414 structural data also argue against a bridging function of UPF3. In the cryo-EM structure of an
415 EJC-UPF3-UPF2-UPF1 complex, UPF1 did not face towards a possible terminating ribosome
416 in the 5' direction, but instead in 3' direction (Melero *et al.*, 2012). Therefore, one could
417 conclude that the interactions between all these proteins do not take place at a single time
418 point during NMD.

419 This raises the question of what UPF3 function is essential for NMD, if it is not its bridging
420 function? Our rescue experiments showed that the middle domain of UPF3B cooperates with
421 the UPF2- and the EJC interaction sites, i.e., its deletion in combination with one other mutation
422 inactivates UPF3B. The middle domain has been described to mediate the interaction of
423 UPF3B with release factor 3 (RF3), but this interaction has not been demonstrated for UPF3A
424 (Neu-Yilik *et al.*, 2017). So, if UPF3A cannot interact with RF3 and also binds weaker to the
425 EJC as noted above, it should be functionally inactive. However, we see no obvious difference
426 between UPF3B and UPF3A in the rescue experiments. These and other observations can, in
427 our view, only be explained with more complex models, which must also consider non-linear
428 relationships and potential auxiliary functions of certain regions of UPF3 (Fig 8).

429 Since the interactions of UPF3 are essential only in combination with each other, we propose
430 that UPF3A and UPF3B exert multiple functions at different time points of NMD and in
431 association with different complexes. We only consider here the previously described
432 interactions of UPF3 with UPF2, the EJC and the release factor 3 (Fig 8B). While it was
433 previously described that UPF3B interacts better than UPF3A with UPF2 (Chan *et al.*, 2009),
434 we find both proteins in the FLAG-UPF2 IP. The amount of UPF3A does not seem to increase
435 when UPF3B is depleted, which could be due to the overexpression of UPF2 in our
436 experimental system. The interaction of UPF3 and UPF2 is also conserved in yeast and is thus

A

B

C

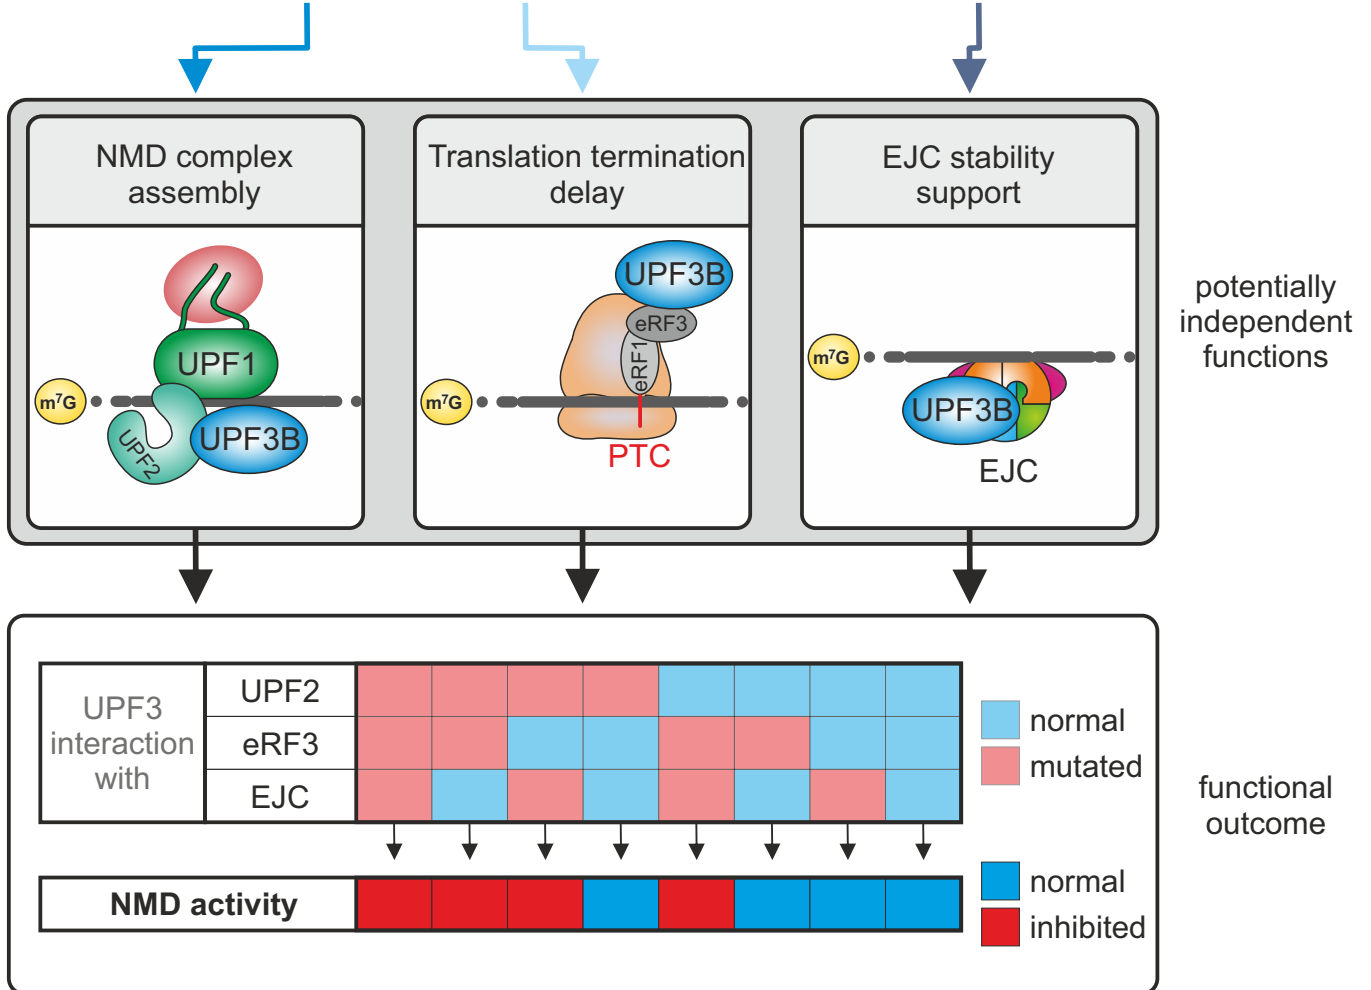

Figure 8 - Model for potentially independent functions of UPF3 in NMD.

A Both UPF3 paralogs UPF3A and UPF3B can elicit NMD and trigger mRNA degradation. We propose a new model where UPF3B exerts multiple functions at different timepoints during NMD.
 B Schematic overview of UPF3B domain structure and the postulated functions. Conservation between UPF3A (UniProt ID: Q9H1J1-1) and UPF3B (UniProt ID: Q9BZ17-2) proteins as calculated via Clustal Omega and Jalview is shown.
 C Via the RRM-like domain in the N-terminus of the protein it interacts with UPF2, which might be important for the assembly of an NMD-inducing complex. The middle domain was ascribed to be responsible for the interaction with eRF3 and potential translation termination delay. The interaction with the EJC via the EBM could stabilize the complex by preventing its interaction with the disassembly factor PYM1. Only if two out of the three functions are ensured, NMD can pursue and degrade the targeted mRNA.

438 likely to have functional significance. However, a UPF3B mutant in which binding to UPF2 was
439 inactivated rescues NMD better than the UPF3B WT.

440 The interaction of the middle domain of UPF3B with RF3 has only recently been described
441 (Neu-Yilik *et al.*, 2017). Again, we find that removing only the middle domain does not
442 substantially inhibit NMD. In combination with an inactivation of the UPF2 binding, the deletion
443 of the middle domain leads to a complete inhibition of the NMD in the rescue assay. This could
444 also happen when exon 4 of UPF3B or UPF3A is removed, which is located at the junction
445 between the UPF2 binding domain and the middle domain. Therefore, UPF3A Δ exon4 would
446 be a naturally occurring, NMD-inactive variant of the UPF3 proteins.

447 How might the different regions and domains communicate with each other and regulate the
448 function of UPF3 in NMD? The function of the middle domain in relation to NMD has not yet
449 been investigated. It is conceivable that UPF3B plays a minor role in translation termination
450 and that the events that trigger NMD can also occur without the middle domain - potentially
451 with a delay (Figure 8c). Therefore, the deletion of the middle domain could be tolerated in
452 isolation but would become fatal in combination with other mutations that impair additional
453 functions. With regard to the EBM, we propose that its binding stabilizes the EJC, for example
454 by preventing the interaction of the EJC with PYM1 (Fig 8C). PYM1 is a known EJC
455 disassembly factor and binds to the EJC at a surface area that overlaps with the EBM binding
456 site (Bono *et al.*, 2004; Buchwald *et al.*, 2010; Gehring *et al.*, 2009). We suggest that in cells
457 rescued with the Δ EBM mutant EJCs are more readily dissociated from the mRNA in the
458 cytoplasm. The concomitant loss of UPF3B's termination function (Δ middle domain, Δ EBM)
459 would have a dramatic effect on NMD efficiency, because NMD would be initiated too slowly.
460 Likewise, the interaction of UPF3 with UPF2 might be important for the assembly of an NMD-
461 inducing complex (Fig 8C) that needs to be timed with translation termination and that leads
462 to NMD activation only in the presence of the EJC. Although these suggestions may not
463 accurately reflect the molecular events during NMD, they illustrate possible functions of the
464 domains of UPF3, particularly in relation to their NMD-inactive combinations (Fig 8). Overall,

465 our observations fit well with a "synthetic lethal" model in which inactivation of any two domains
466 together disrupts UPF3 activity.

467 One factor whose function needs to be examined in more detail in the context of UPF3 is
468 CASC3. Our mass spectrometry analysis shows that CASC3 immunoprecipitates very well
469 with UPF2 in wildtype cells. CASC3 still partially precipitates with UPF2 in UPF3B KO cells,
470 although the interaction of the other EJC factors is reduced to background levels. In previous
471 work, we observed that UPF3B interacts less well with the EJC when CASC3 is knocked out
472 (Gerbracht *et al.*, 2020). This indicates that an interaction between CASC3 and the UPF3
473 proteins exists that is not well understood so far. What kind of interaction this is and what
474 function it has will be interesting to address in future experiments.

475 Our own work and the work of Yi *et al.* have re-examined the functions of the human UPF3
476 paralogues UPF3A and UPF3B (Yi *et al.*, 2021). Together, the studies confirmed some
477 previous findings and disconfirmed others, thereby successfully (re-)defining the role of UPF3
478 proteins in human cells. A few questions remain unanswered and need to be addressed in the
479 future, for example how exactly the middle domain supports NMD. As described above, our
480 results have implications for the understanding of the NMD mechanism, as they are
481 incompatible with, and thus exclude, certain models of NMD. In addition, they may also help
482 to better understand the link between UPF3B and intellectual disability and which domains of
483 UPF3A modulate the severity of the disease and may therefore be potential targets for therapy.

484

485

486 **Materials and Methods**

487 **Cell Culture**

488 Flp-In-T-REx-293 (human, female, embryonic kidney, epithelial; Thermo Fisher Scientific,
489 RRID:CVCL_U427) cells were cultured in high-glucose, GlutaMAX DMEM (Gibco)
490 supplemented with 9% fetal bovine serum (Gibco) and 1x Penicillin Streptomycin (Gibco). The
491 cells were cultivated at 37°C and 5% CO₂ in a humidified incubator. The generation of
492 knockout and stable cell lines is described below and all cell lines are summarized in [Dataset](#)
493 [EV6](#).

494 **siRNA-mediated knockdowns**

495 For reverse transfection the cells were seeded at a density of 2.5x10⁵ cells per well. The
496 transfection solution contained 2.5 µl Lipofectamine RNAiMAX and 60 pmol of the respective
497 siRNAs. For the UPF3A and UPF3B knockdowns 30 pmol of both belonging siRNAs were
498 used. In preparation for mass spectrometry, 2.5x10⁶ were reverse transfected in 10 cm plates
499 using 6.25 µl Lipofectamine RNAiMAX and 150-200 pmol siRNA (or half of it for each of the
500 two siRNAs for UPF3A or UPF3B). All siRNAs used in this study are listed in [Dataset EV6](#).

501 **Plasmid transfection**

502 For each stable transfection 2.5-3.0x10⁵ cells were seeded one day prior transfection in 6-
503 wells. To express the N-terminally FLAG-tagged protein constructs and reporter mRNAs for
504 northern blotting, they were stably integrated using the PiggyBac (PB) Transposon system with
505 the cumate-inducible PB-CuO-MCS-BGH-EF1-CymR-Puro vector. This vector was modified
506 from the original vector (PB-CuO-MCS-IRES-GFP-EF1α-CymR-Puro (System Biosciences))
507 by replacing the IRES-GFP cassette with a BGH polyA signal. Per well 1.0 µg of the respective
508 PB vector and 0.8 µg PB Transposase were transfected using a calcium phosphate-based
509 system with BES buffered saline (BBS). Additionally, 0.5 µg of pCI-maxGFP was transfected
510 as a visual feedback for transfection efficiency. 48 h later, the cells were pooled in 10 cm plates
511 and selected for positive cells by incubation in media containing 2 µg/ml puromycin for a week.

512 To induce expression of the constructs, 30 µg/ml cumate was added and the cells were
513 harvested after 72h for continuing experiments.

514 The mRNA reporter constructs β-globin WT and β-globin PTC are available on Addgene (IDs
515 108375-108376). All vectors used in this study are listed in [Dataset EV6](#).

516 **Generation of knockout cells using CRISPR-Cas9**

517 The knockouts were performed using the Alt-R CRISPR-Cas9 system (Integrated DNA
518 Technologies) and reverse transfection of a Cas9:guideRNA ribonucleoprotein complex using
519 Lipofectamine RNAiMAX (Thermo Fisher Scientific) according to the manufacturer's protocol.
520 The crRNA sequence (Integrated DNA Technologies) to target UPF3B was
521 /AltR1/rArGrArUrArArGrCrArGrGrArUrCrGrCrArArCrArGrUrUrUrUrArGrArGrCrUrArUrGrCrU/
522 AltR2/. For UPF3A the crRNA sequences were /AltR1/rCrCrGrCrArArCrCrGrGrArGrGrArC
523 rGrArArGrUrGrUrUrUrUrArGrArGrCrUrArUrGrCrU/AltR2/ for clone 1 and /AltR1/rGrCrGrGr
524 UrGrGrArArCrUrGrCrArCrUrUrCrUrArGrUrUrUrUrArGrArGrCrUrArUrGrCrU/AltR2/ for clone
525 2. Reverse transfection was performed on 1.5×10^5 cells per crRNA in 12-well plates. 48 h after
526 transfection the cells were trypsinized, counted and seeded at a mean density of a single cell
527 per well in 96-well plates. Cell colonies originating from a single clone were then screened via
528 Western blot and genome editing of UPF3A and UPF3B was analyzed on the genomic level
529 via DNA extraction and Sanger sequencing. Alterations on the transcript level were analyzed
530 via RNA extraction followed by reverse transcription and Sanger sequencing.

531 **DNA and RNA extraction**

532 Genomic DNA extraction using QuickExtract DNA Extraction Solution (Lucigen) was
533 performed according to manufacturer's instruction. For RNA extraction cells were harvested
534 with 1 ml RNAsolv reagent (Omega Bio-Tek) per 6 well and RNA was isolated according to
535 manufacturer's instruction, with the following changes: instead of 200 µl chloroform, 150 µl 1-
536 Bromo-3-chloropropane (Sigma-Aldrich) was added to the RNAsolv. Additionally, in the last
537 step the RNA pellet was dissolved in 20 µl RNase-free water by incubating for 10 min on a
538 shaking 65 °C heat block.

539 **Western blotting**

540 SDS-polyacrylamide gel electrophoresis and immunoblot analysis were performed using
541 protein samples harvested with RIPA buffer (50 mM Tris/HCl pH 8.0, 0.1% SDS, 150 mM NaCl,
542 1% IGEPAL, 0.5% deoxycholate) or samples eluted from Anti-FLAG M2 magnetic beads. For
543 protein quantification, the Pierce Detergent Compatible Bradford Assay Reagent (Thermo
544 Fisher Scientific) was used. All antibodies used in this study are listed in [Dataset EV6](#).
545 Detection was performed with Western Lightning Plus-ECL (PerkinElmer) or ECL Select
546 Western Blotting Detection Reagent (Amersham) and the Vilber Fusion FX6 Edge imaging
547 system (Vilber Lourmat).

548 **Semi-quantitative and quantitative reverse transcriptase (RT)-PCR**

549 Reverse transcription was performed with 1-4 μ g of total RNA in a 20 μ l reaction volume with
550 10 μ M VNN-(dT)₂₀ primer and the GoScript Reverse Transcriptase (Promega). For the semi-
551 quantitative end-point PCRs the MyTaq Red Mix (Bioline) was used. Quantitative RT-PCRs
552 were performed with the GoTaq qPCR Master Mix (Promega), 2% of cDNA per reaction, and
553 the CFX96 Touch Real-Time PCR Detection System (Bio-Rad). Each biological replicate was
554 repeated in technical triplicates and the average Ct (threshold cycle) value was measured.
555 When isoform switches were measured, values for NMD sensitive isoforms were normalized
556 to the canonical isoforms to calculate Δ Ct. For differentially expressed genes, the
557 housekeeping gene C1orf43 values were subtracted from the target value to receive the Δ Ct.
558 To calculate the mean log₂ fold changes three biologically independent experiments were
559 used. The log₂ fold changes are visualized as single data points and mean. All primers used
560 in this study are listed in [Dataset EV6](#).

561 **RNA-sequencing and computational analyses**

562 Four different RNA-seq experiments were performed: 1) unaltered Flp-In T-REx 293 wild type
563 (WT) cells and WT cells overexpressing the UPF3A WT construct via the PB-Transposase
564 system. 2) Flp-In T-REx 293 wild type (WT) cells transfected with Luciferase siRNA and the
565 UPF3A KO clones 14 and 20 treated with either Luciferase or UPF3B siRNAs. 3) The control

566 Flp-In T-REx 293 wild type (WT) cells with a Luciferase KD and the UPF3B KO clone 90
567 transfected with Luciferase or UPF3A siRNAs. 4) WT cells transfected with Luciferase siRNA
568 and the two UPF3 double KO cell lines 1 and 2 transfected with either Luciferase or UPF3B
569 siRNAs. RNA was purified using peqGOLD TriFast (VWR Peqlab; for UPF3B KO samples) or
570 the Direct-zol RNA MiniPrep kit including the recommended DNase I treatment (Zymo
571 Research; all other samples) according to manufacturer's instructions. Three biological
572 replicates were analyzed for each sample.

573 The Lexogen SIRV Set3 Spike-In Control Mix (SKU: 051.0x; for UPF3B KO samples) or ERCC
574 RNA Spike-In Mix (for all other samples) that provides a set of external RNA controls was
575 added to the total RNA to enable performance assessment. The Spike-Ins were used for
576 quality control purposes, but not used for the final analysis of DGE, DTU or AS.

577 Using the Illumina TruSeq Stranded Total RNA kit library preparation was accomplished. This
578 includes removing ribosomal RNA via biotinylated target-specific oligos combined with Ribo-
579 Zero gold rRNA removal beads from 1 µg total RNA input. Cytoplasmic and mitochondrial
580 rRNA gets depleted by the Ribo-Zero Human/Mouse/Rat kit. After a purification step, the RNA
581 gets cleaved and fragmented. These fragments are then reverse transcribed into first strand
582 cDNA using reverse transcriptase and random primers. In the next step, using DNA
583 Polymerase I and RNase H second strand cDNA synthesis is performed. The resulting cDNA
584 fragments then have the extension of a single 'A' base and adapter ligation. To create the final
585 cDNA library the products are purified and enriched with PCR. Next library validation and
586 quantification (Agilent tape station) are performed, followed by pooling of equimolar amounts
587 of library. The pool itself was then quantified using the Peqlab KAPA Library Quantification Kit
588 and the Applied Biosystems 7900HT Sequence Detection System and sequenced on an
589 Illumina HiSeq4000 sequencing instrument with an PE75 protocol (UPF3B KO samples) or
590 Illumina NovaSeq6000 sequencing instrument with an PE100 protocol (all other samples).

591 Reads were aligned against the human genome (version 38, GENCODE release 33 transcript
592 annotations (Frankish *et al.*, 2019) supplemented with SIRVomeERCCome annotations from

593 Lexogen; obtained from <https://www.lexogen.com/sirvs/download/>) using the STAR read
594 aligner (version 2.7.3a) (Dobin *et al.*, 2013). Transcript abundance estimates were computed
595 with Salmon (version 1.3.0) (Patro *et al.*, 2017) with a decoy-aware transcriptome. After the
596 import of transcript abundances, differential gene expression analysis was performed with the
597 DESeq2 (Love *et al.*, 2014) R package (version 1.28.1) with the significance thresholds
598 $|\log_2\text{FoldChange}| > 1$ and adjusted p-value (padj) < 0.05 . Differential splicing was detected with
599 LeafCutter (version 0.2.9) (Li *et al.*, 2018) with the significance thresholds $|\text{deltapsi}| > 0.1$ and
600 adjusted p-value (p.adjust) < 0.05 . Differential transcript usage was computed with
601 IsoformSwitchAnalyzeR (version 1.10.0) and the DEXSeq method (Anders *et al.*, 2012; Ritchie
602 *et al.*, 2015; Robinson & Oshlack, 2010; Soneson *et al.*, 2015; Vitting-Seerup & Sandelin, 2017,
603 2019). Significance thresholds were $|\text{dIF}| > 0.1$ and adjusted p-value (isoform_switch_q_value)
604 < 0.05 .

605 PTC status of transcript isoforms with annotated open reading frame was determined by
606 IsoformSwitchAnalyzeR using the 50 nucleotide (nt) rule of NMD (Huber *et al.*, 2015; Vitting-
607 Seerup *et al.*, 2014; Vitting-Seerup & Sandelin, 2017; Weischenfeldt *et al.*, 2012). Isoforms
608 with no annotated open reading frame in GENCODE were designated “NA” in the PTC
609 analysis.

610 All scripts and parameters for the RNA-Seq analysis are available at GitHub
611 [<https://github.com/boehmv/UPF3>]. Overlaps of data sets were represented via nVenn (Perez-
612 Silva *et al.*, 2018) or the ComplexHeatmap package (version 2.6.2) (Gu *et al.*, 2016). Integrative
613 Genomics Viewer (IGV) (version 2.8.12) (Robinson *et al.*, 2011) snapshots were generated
614 from mapped reads (BAM files) converted to binary tiled data (tdf), using Alfred (Rausch *et al.*,
615 2019) with resolution set to 1 and IGVtools.

616 **SILAC and mass spectrometry**

617 HEK293 WT cells and the UPF3 dKO clone 2 expressing either FLAG-tagged GST or UPF2
618 were labeled by culturing them for at least 5 passages in DMEM for SILAC medium (Thermo
619 Fisher Scientific) supplemented with 9% FBS (Silantes), 1% Penicillin-Streptomycin and the

620 labeled amino acids Lysin and Arginine at final concentrations of 0.798 mmol/L and 0.393
621 mmol/L, respectively. The three conditions were “light” (unlabeled Lys/ Arg), “medium” (Lys4/
622 Arg6) and “heavy” (Lys8/ Arg10). Unlabeled proline was added in all conditions to prevent
623 enzymatic Arginine-to-Proline conversion.

624 **Experimental setup for SILAC with FLAG-tagged UPF2**

625 Expression of FLAG-GST and FLAG-UPF2 was induced for 72 h with 1x cumate. The cells
626 lysed in 250 – 400 µl Buffer E with 1 µg/ml RNase and sonicated using the Bandelin Sonopuls
627 mini20 with 15x 1s pulses at 50% amplitude with a 2.5 mm tip. Protein concentrations were
628 measured using the Bradford assay and protein samples containing 1.6-1.7 mg/ml total protein
629 were diluted. 600 µl of these samples were incubated with 30 µl Anti-FLAG M2 magnetic beads
630 (Sigma) for 2 h on an overhead shaker at 4 °C. The beads were then washed three times for
631 5 min with mild EJC-Buffer before eluting twice with 22 µl of a 200 µg/ml dilution of FLAG-
632 peptides (Sigma) in 1x TBS for 10 min at RT and 200 rpm each elution step. Another elution
633 with 1x SDS loading buffer was performed to analyze pull down efficiency via Western blot.
634 The FLAG-peptide eluates were then mixed as followed: 7 µl of both light conditions, 14 µl
635 medium and 14 µl heavy. 1 volume of SP3 (10% SDS in PBS) was added and the samples
636 were reduced with 5 mM DTT and alkylated with 40 mM CAA.

637 Tryptic protein digestion was achieved by following a modified version of the single pot solid
638 phase-enhanced sample preparation (SP3) (Hughes *et al.*, 2014). In brief, paramagnetic Sera-
639 Mag speed beads (Thermo Fisher Scientific) were added to the reduced and alkylated protein
640 samples and then mixed 1:1 with 100% acetonitrile (ACN). Protein-beads-complexes form
641 during the 8 min incubation step, followed by capture using an in-house build magnetic rack.
642 After two washing steps with 70% EtOH, the samples were washed once with 100% ACN.
643 Then they were air-dried, resuspended in 5 µl 50 mM Triethylammonium bicarbonate
644 supplemented with trypsin and LysC in an enzyme:substrate ratio of 1:50 and incubated for 16
645 h at 37°C. The next day the beads were again resuspended in 200 µl ACN and after 8 min
646 incubation placed on the magnetic rack. Tryptic peptides were washed with 100% ACN and

647 air-dried before dissolved in 4% DMSO and transfer into 96-well PCR tubes. The last step was
648 the acidification with 1 μ l of 10% formic acid, then the samples were ready for mass spec
649 analysis.

650 Proteomics analysis was performed by the proteomics core facility at CECAD via data-
651 dependent acquisition using an Easy nLC1200 ultra high-performance liquid chromatography
652 (UHPLC) system connected via nano electrospray ionization to a Q Exactive Plus instrument
653 (all Thermo Scientific) running in DDA Top10 mode. Based on their hydrophobicity the tryptic
654 peptides were separated using a chromatographic gradient of 60 min with a binary system of
655 buffer A (0.1% formic acid) and buffer B (80% ACN, 0.1% formic acid) with a total flow of 250
656 nl/min. For the separation in-house made analytical columns (length: 50 cm, inner diameter:
657 75 μ m) containing 2.7 μ m C18 Poroshell EC120 beads (Agilent) that were heated to 50 $^{\circ}$ C in
658 a column oven (Sonation) were used. Over a time period of 41 min Buffer B was linearly
659 increased from 3% to 27% and then more rapidly up to 50% in 8 min. Finally, buffer B was
660 increased to 95% within 1 min followed by 10 min at 95% to wash the analytical column. Full
661 MS spectra (300-1,750 m/z) were accomplished with a resolution of 70,000, a maximum
662 injection time of 20 ms and an AGC target of 3e6. In each full MS spectrum, the top 10 most
663 abundant ions were selected for HCD fragmentation (NCE:27) with a quadrupole isolation
664 width of 1.8 m/z and 10 s dynamic exclusion. The MS/MS spectra were then measured with a
665 35,000 resolution, an injection time of maximum 110 ms and an AGC target of 5e5.

666 The MS RAW files were then analyzed with MaxQuant suite (version 1.5.3.8) on standard
667 settings with the before mentioned SILAC labels (Cox & Mann, 2008). By matching against the
668 human UniProt database the peptides were then identified using the Andromeda scoring
669 algorithm (Cox *et al.*, 2011). Carbamidomethylation of cysteine was defined as a fixed
670 modification, while methionine oxidation and N-terminal acetylation were variable
671 modifications. The digestion protein was Trypsin/P. A false discovery rate (FDR) < 0.01 was
672 used to identify peptide-spectrum matches and to quantify the proteins. Data processing and
673 statistical analysis was performed in the Perseus software (version 1.6.1.1) (Tyanova *et al.*,

674 2016). Using the One-sample t-test the significantly changed proteins were identified ($H_0 = 0$,
675 fudge factor $S_0 = 0.2$). Visualization was performed with RStudio (version 1.2.5033).

676 **Label-free quantitative mass spectrometry**

677 Twenty-four hours before expression of the FLAG-tagged constructs, the HEK 293 WT cells
678 were treated with Luciferase siRNA and the UPF3B KO clone 90 and UPF3 dKO clone 1 cells
679 were treated with siRNAs targeting residual UPF3B. The expression of either FLAG-GST or
680 FLAG-UPF2 in WT cells and FLAG-UPF2 in the clones 90 and 1 was induced for 48 h with 1x.
681 Lysis and sample preparation were performed as described above. MS analysis was
682 performed as described above with a slightly adjusted gradient as followed: 3 – 30% B in 41
683 min, 30 – 50% B in 8 min, 50-95% B in 1 min, followed by 10 min washing at 95%. LFQ values
684 were calculated using the MaxLFQ algorithm (Cox *et al.*, 2014) in MaxQuant. Significantly
685 changed proteins were identified by two-sample *t*-testing (fudge factor $S_0 = 0.2$).

686 **Northern Blotting**

687 The cells were harvested in RNAsolv reagent and total RNA extraction was performed as
688 described above. 3.0 μg total RNA were resolved on a 1% agarose/0.4 M formaldehyde gel
689 using the tricine/triethanolamine buffer system (Mansour & Pestov, 2013). Next a transfer on
690 a nylon membrane (Roth) in 10x SSC followed. The blot was incubated overnight at 65°C in
691 Church buffer containing [α -32P]-GTP body-labeled RNA-probes for mRNA reporter detection
692 (Voigt *et al.*, 2019). Ethidium bromide stained 28S and 18S rRNA served as loading controls.
693 RNA signal detected with the Typhoon FLA 7000 (GE Healthcare) was quantified in a semi-
694 automated manner using the ImageQuant TL 1D software with a rolling-ball background
695 correction. EtBr-stained rRNA bands were quantified with the Image Lab 6.0.1 software (Bio-
696 Rad). Signal intensities were normalized to the internal control (rRNA) before calculation of
697 mean values. The control condition was set to unity (TPI WT for reporter assays), quantification
698 results are shown as data points and mean.

699 **Protein conservation**

700 UPF3A (UniProt ID: Q9H1J1-1) and UPF3B (UniProt ID: Q9BZI7-2) protein sequences were
701 aligned using Clustal Omega (<https://www.ebi.ac.uk/Tools/msa/clustalo/>) (Goujon *et al.*, 2010;
702 Sievers *et al.*, 2011), viewed using Jalview (Waterhouse *et al.*, 2009), the conservation score
703 extracted and used for visualization.

704 **Data Presentation**

705 Quantifications and calculations for other experiments were performed - if not indicated
706 otherwise - with Microsoft Excel (version 1808) or R (version 4.0.4) and all plots were
707 generated using IGV (version 2.8.12), GraphPad Prism 5, ggplot2 (version 3.3.3) or
708 ComplexHeatmap (version 2.6.2) (Gu *et al.*, 2016).

709 **Data Availability**

710 The datasets and computer code produced in this study are available in the following
711 databases:

- 712 • RNA-Seq data for UPF3B KO samples: ArrayExpress E-MTAB-10711
713 (<https://www.ebi.ac.uk/arrayexpress/experiments/E-MTAB-10711>)
- 714 • RNA-Seq data for UPF3 dKO samples: ArrayExpress E-MTAB-10716
715 (<https://www.ebi.ac.uk/arrayexpress/experiments/E-MTAB-10716>)
- 716 • RNA-Seq data for UPF3A KO/OE samples: ArrayExpress E-MTAB-10718
717 (<https://www.ebi.ac.uk/arrayexpress/experiments/E-MTAB-10718>)
- 718 • Mass spectrometry proteomics data: PRIDE PXD027120
719 (<https://www.ebi.ac.uk/pride/archive/projects/PXD027120>)
- 720 • Codes used in this study: GitHub (<https://github.com/boehmv/UPF3>)

721 All relevant data supporting the key findings of this study are available within the article and its
722 Expanded View files or from the corresponding author upon reasonable request.

723 **Acknowledgements**

724 We thank members of the Gehring lab for discussions and reading of the manuscript. We also
725 thank Marek Franitza and Christian Becker (Cologne Center for Genomics, CCG) for preparing
726 the sequencing libraries and operating the sequencer. This work was supported by grants from
727 the Deutsche Forschungsgemeinschaft to C.D. (DI 1501/8-1, DI1501/8-2) and N.H.G (GE
728 2014/6-2 and GE 2014/10-1) and by the Center for Molecular Medicine Cologne (CMMC,
729 Project C 07; to N.H.G.). V.B. was funded under the Institutional Strategy of the University of
730 Cologne within the German Excellence Initiative. N.H.G. acknowledges funding by a
731 Heisenberg professorship (GE 2014/7-1 and GE 2014/13-1) from the Deutsche
732 Forschungsgemeinschaft. C.D was kindly supported by the Klaus Tschira Stiftung gGmbH
733 (00.219.2013). This work was supported by the DFG Research Infrastructure as part of the
734 Next Generation Sequencing Competence Network (project 423957469). NGS analyses were
735 carried out at the production site WGGC Cologne.
